ACKNOWLEDGEMENTS

I thank my major advisor, Timothy H. Bonner, who has been my mentor throughout my time at Texas State University. I also thank my committee members who provided comments on my dissertation. Thank you to all of my past and present lab mates as well as undergraduates who have helped on all of my projects during my time as a masters and PhD student. This work is truly collaborative in nature and does not represent one person's accomplishments. Lastly, to my family and friends, without you this would all be pointless.

ABSTRACT

Factors influencing fish community structure are numerous, complex, and interdependent. Structuring mechanisms of aquatic communities fall within four broad classes (i.e., zoogeography and deep-evolution, local abiotic and biotic phenomena, autecology of individual species, and biotic interactions among fishes) and explain why fishes are found in local and regional communities. The common theme among chapters is identification of patterns that aid in understanding contributions of the four broad classes in regulating fish community structure. A unique contribution of my work is the application of theoretical community ecology framework across multiple scales, from individuals to ecoregions, using descriptive and manipulative field and laboratory experiments. Chapter 1 provides updated drainage checklist and keys for Texas inland fishes, which provides accurate identification of study organisms. Chapter 2 establishes standardized and adaptable framework for assessing and reporting fish-environment associations. The framework was then applied to 11 habitat variables and 146 inland fishes of Texas. Remaining chapters focus on identification of mechanisms that maintain fish community structure, including water quantity and water quality within spring complexes (Chapter 3--San Antonio historical and current fish community, Chapter 4--Testing expectations of an understudied spring fish community using models and historical data) and biotic factors (Chapter 5--Temperature-mediated feeding between spring-associated and riverine-associated congeners, with implications for community segregation).

I. DRAINAGE BASIN CHECKLISTS AND DICHOTOMOUS KEYS FOR INLAND FISHES OF TEXAS

Citation – Craig, C.A. and Bonner, T.H., 2019. Drainage basin checklists and dichotomous keys for inland fishes of Texas. ZooKeys, 874 (2019): 31

Abstract

Species checklists and dichotomous keys are valuable tools that provide many services for ecological studies and management through tracking native and non-native species through time. We developed nine drainage basin checklists and dichotomous keys for 196 inland fishes of Texas, consisting of 171 native fishes and 25 non-native fishes. Our checklists were updated from previous checklists and revised using reports of new established native and non-native fishes in Texas, reports of new fish occurrences among drainages, and changes in species taxonomic nomenclature. We provided the first dichotomous keys for major drainage basins in Texas. Among the 171 native inland fishes, 6 species are considered extinct or extirpated, 13 species are listed as threatened or endangered by U.S. Fish and Wildlife Service, and 59 species are listed as Species of Greatest Conservation Need (SGCN) by the state of Texas. Red River drainage basin was the most speciose with 120 fishes. Rio Grande & Pecos drainage basin had the greatest number of threatened or endangered fishes ($N = 7$), and the greatest number of SGCN fishes ($N = 28$). We revised drainage basin occurrences for 77 species. Drainage basin checklists and dichotomous keys provide finer resolution of species distributions within the geopolitical boundaries of Texas and can reduce probability of errors in fish identification errors by removing species not occurring within a natural boundary.

Introduction

Species checklists consolidate biodiversity records using standardized taxonomic nomenclature and updated species occurrences within pre-defined boundaries (Fleishman et al. 2006; Martellos and Nimis 2015). Benefits of checklists include use in ecological studies and natural resources management, such as assessments of global patterns in species richness (Gaston 2000), identification of biodiversity hotspots (Kent et al. 2002), occurrences for species distribution models (Caicco et al. 1995), and expansion and contraction of native and non-native species (Lee et al. 2008; Magurran et al. 2010). Often coupled with checklists, dichotomous keys facilitate species identification using a series of distinguishing characteristics (Griffing 2011). Dichotomous keys usually are created for taxa within geopolitical boundaries (e.g., Hubbs et al. 2008); however, geopolitical boundaries often are arbitrary to species distributions (Forman 2014). Recent development and use of dichotomous keys along natural boundaries, such as drainage basin (Worsham et al. 2016), provide finer resolution on species distributions and reduce probability of identification errors by removing species not occurring within a natural boundary.

Within Texas, Evermann and Kendall (1894) published the first checklist of freshwater fishes. A revised checklist was published by Baughman (1950a, 1950b), using standardized taxonomic nomenclature provided by Jordan et al. (1930). Jurgens and Hubbs (1953) were the first to publish a checklist using standardized taxonomic nomenclature provided by American Fisheries Society Committee on Names of Fishes (Chute et al. 1948). This checklist was periodically revised by Hubbs (i.e., Hubbs 1957, 1958, 1961, 1972, 1976, 1982). Knapp (1953) published a checklist and the first

dichotomous key for freshwater fishes of Texas. Texas drainage basin checklists were published for western Gulf Slope drainage basins (Conner and Suttkus 1986), Mississippi River drainage basins (Cross et al. 1986), and Rio Grande drainage basin (Smith and Miller 1986). Statewide checklist and dichotomous key were revised by Hubbs et al. (1991) and Hubbs et al. (2008).

Revisions of checklists for freshwater fishes of Texas were necessary through time to accommodate additions of previously unreported species, multiple species described from a single species, and non-native species introductions (Hanks and McCoid 1988; Eisenhour 2004; Gallaway et al. 2008) and to accommodate removal of introduced fishes that did not establish populations (Howells 2001). In addition, species distributions were updated to document range expansions (e.g., *Percina carbonaria*, Hubbs et al. 2008), range contractions (e.g., *Ictalurus lupus*, Kelsch and Hendricks 1990), and name changes (e.g., *Micropterus treculi* to *Micropterus treculii*) using standardized taxonomic nomenclature (e.g., Nelson et al. 2004). Since Hubbs et al. (2008), American Fisheries Society and American Society of Ichthyologists and Herpetologists (AFS-ASIH) Committee of Names of Fishes published a revised common and scientific names list (Page et al. 2013), new native species were reported within Texas (e.g., Craig et al. 2015), a fish name was synonymized (Echelle et al. 2013), introduced species became established (e.g., Cohen et al. 2014), and species ranges expanded (e.g., Dautreuil et al. 2016) and contracted (e.g., Craig et al. 2017).

Purposes of this paper were to develop drainage basin checklists and dichotomous keys for Texas freshwater fishes. As with previous revisions, we updated the statewide checklist and dichotomous key with new species, removal of species, and range changes.

However, our checklists and dichotomous keys differ markedly from previous revisions. We identified fishes as inland, rather than freshwater, and divided the geopolitical boundary into natural boundaries using major drainage basins. Texas is particularly well suited for drainage basin checklists and keys because majority of the drainage basins became independent of one another during the early Holocene (i.e., river termini in Gulf of Mexico bays), generally restricting freshwater fish movement among drainage basins. As such, fishes are rarely homogeneously distributed among all drainage basins, with 41% of fishes restricted to one or two drainage basins (Conner and Suttkus 1986; Hubbs et al. 2008).

Methods

Development of a freshwater fish checklist is a challenge within natural or geopolitical boundaries having fresh and marine environments (Ross 2001; Moyle 2002). Inclusions of marine fishes on a freshwater fish checklist are subjective (Ross 2001). Knapp (1953) included marine fishes if observed in waters with salinities < 2 ppt. Hubbs et al. (1991) included marine fishes if found in “low salinity habitats”. Using salinity as an objective measure is limiting. Several fishes found in upper reaches of the Canadian River, Red River, Brazos River, Colorado River, and Pecos River inhabit saline waters with salinities exceeding 50 ppt at times (Echelle et al. 1972), so excluding fishes based on salinity tolerances would exclude several species not known to inhabit marine or estuarine environments. Avoiding salinity as a measure, we used the term “inland” instead of “freshwater” to represent fishes found in Texas rivers generally upstream from transitory freshwater-saltwater boundaries. We accepted fishes as inland if they hatch,

feed, and reproduce within inland waters (i.e., all water bodies upstream of river termini). We also accepted two forms of marine fishes as inland fishes: diadromous fishes (i.e., *Anguilla rostrata*, *Agonostomus monticola*, and *Trinectes maculatus*) and fishes with reported self-sustaining populations within inland waters (e.g., *Syngnathus scovelli*, Martin et al. 2013). Our acceptance of fishes as inland oversimplifies the complex and dynamic relationship of fish communities within estuarine systems of the Gulf of Mexico (Gelwick et al. 2001); therefore, our inland fish checklists underestimate the number of fishes encountered in estuarine systems.

Drainage basins were defined as major independent rivers that flow directly into the Gulf of Mexico (i.e., Sabine & Neches, Trinity & San Jacinto, Brazos, Colorado & Lavaca, Guadalupe & San Antonio, Nueces, and Rio Grande & Pecos) or beyond Texas borders (i.e., Canadian and Red) (Figure 1.1). Drainage basin checklists were developed using specific (Conner and Suttkus 1986; Cross et al. 1986; Smith and Miller 1986) and generalized (Hubbs et al. 2008) drainage basin checklists. Checklists were consolidated and updated based on drainage basin distribution records for each species using Texas Natural History Collections database (Hendrickson and Cohen 2015), published consolidated species accounts (e.g., Lee et al. 1980), and published individual species range accounts (e.g., Wilde and Bonner 2000). We only included species from previous checklists if species were recognized by Page et al. (2013) to minimize taxonomic inflation (Isaac et al. 2004). New species were added to checklists and keys based on published accounts of self-sustaining populations (*Ameiurus nebulosus*; Craig et al. 2015). A species was designated as native if it occurs within at least one Texas drainage basin without human aid. Transient border species (i.e., *Pimephales notatus*, Lee and

Shute 1980; *Hiodon tergisus*, Gilbert 1980; *Cyprinella panarcys*, Pinion et al. 2018) with occurrences in boundary waters of Texas were excluded because of uncertainty in self-sustaining populations. At least 80 non-native fishes have been introduced into Texas drainage basins; however, the majority did not establish self-sustaining populations (Howells 2001). Non-native fishes were included in drainage basin checklists if we had evidence (i.e., publications, personal communications) of self-sustaining populations or regular stocking (e.g., *Ctenopharyngodon idella*). Fishes considered extinct (IUCN 2018) were included in the checklist but excluded from keys because of low likelihood of encounter.

Each drainage basin dichotomous key consists of family and species keys. We developed novel distinguishing characteristics for family and species keys along with modifying and using characteristics from original species descriptions (e.g., Eisenhour 2004) and existing keys (e.g., Robison and Buchanan 1988; Sublette et al. 1990; Boschung and Mayden 2004; Thomas et al. 2007; Hubbs et al. 2008). Distinguishing characteristics were comprised of external and internal morphologies, meristics, and color patterns of adult fishes. Each couplet lists the most pronounced distinguishing characteristic first, followed by additional, generally less pronounced, distinguishing characteristics.

Results and Discussion

The composite drainage basin checklist included 196 inland fishes, representing 79 genera and 30 families (Table 1.1). Dichotomous keys were developed for nine drainage basins (Appendix 1.1). The number of inland fishes, based on our definition herein,

reported in previous checklists ranged from 93 (Evermann and Kendall 1894) to 191 (Hubbs et al. 2008). Hubbs et al. (2008) and our composite drainage basin checklist were the most similar but with differences. Our checklist included three fishes reported in Texas after 2008: native *Ameiurus nebulosus* (Craig et al. 2015), non-native *Xiphophorus variatus* (Cohen et al. 2014), and non-native *Hypophthalmichthys nobilis* (T. Bister, Texas Parks and Wildlife Inland Fisheries, personal communication 10 March 2019). Fishes included by Hubbs et al. (2008) and excluded from our checklist were *Cyprinella* sp., *Cycleptus* sp., and *Ictalurus* sp., because Page et al. (2013) did not recognize these three putative species. Also based on Page et al. (2013), fish names were changed for three species: *Herichthys cyanoguttatus*, *Erismyzon claviformis*, and *Menidia audens*. One species (i.e., *Gambusia clarkhubbsi*) was included by Hubbs et al. (2008) and Page et al. (2013) but excluded from our checklist, because *G. clarkhubbsi* was later determined to be a junior synonym for *Gambusia krumholzi* (Echelle et al. 2013). *Gambusia krumholzi* replaced *G. clarkhubbsi* in our checklist. We excluded 8 non-native fishes reported by Hubbs et al. (2008), each lacking evidence of self-sustaining populations: *Scardinius erythrophthalmus*, *Agamyxis pectinifrons*, *Platydoras armatulus*, *Pterygoplichthys multiradiatus*, *Esox lucius*, *Perca flavescens*, *Sander canadensis*, and *Tilapia zillii*. Our checklist includes updated distributions of several fishes from previous checklists. Our checklist has 77 fishes with different drainage basin distributions compared to the drainage basin checklists of Conner and Suttkus (1986), Cross et al. (1986), and Smith and Miller (1986). Although interpreted from generalized descriptions, we determined our checklist has different drainage basin distributions of at least 46 fishes compared to Hubbs et al. (2008). Differences in distributions of fishes are largely due to the

generalized nature of Hubbs et al. (2008) descriptions, but also include range expansions and contractions.

Our composite drainage basin checklist has 171 native and 25 non-native inland fishes. Among native species, three fishes (i.e., *Notropis orca*, *Gambusia amistadensis*, and *Gambusia georgei*) are considered extinct, and three fishes (i.e., *Notropis simus*, *Oncorhynchus clarkii*, and *Gambusia senilis*) are considered extirpated (Hubbs et al. 2008). Thirteen fishes are listed as threatened and endangered by U.S. Fish and Wildlife Service (USFWS), and 59 fishes are listed as Species of Greatest Conservation Need (SGCN, Texas Parks and Wildlife 2012). Number of native fishes by drainage basin ranged from 32 in the Canadian to 111 in the Red. Rio Grande & Pecos had the greatest number of USFWS threatened and endangered fishes (N = 7) and SGCN fishes (N = 28). Number of non-native fishes by drainage basin ranged from five in the Canadian to 20 in the Guadalupe & San Antonio. Origins of non-native fishes are from marine waters of Texas and from inland waters of North America and other continents (Table 1.2). Based on published accounts, non-native fishes were introduced for human consumption and sport (Nico and Fuller 1999), bait bucket releases (Howells 2001), vegetation control (Guillory and Gasaway 1978), accidental aquaculture releases (Howells 2001), and aquarium releases (Cohen et al. 2014).

A limitation of the drainage basin checklist and dichotomous keys is that documentation of species by drainage is incomplete. As such, our drainage basin checklists and dichotomous keys should be viewed as living documents and will need periodic updates. While using a drainage basin key, we caution users that the key only includes species known to occur within a basin, and the drainage basin might include

more species. If an unknown specimen does not seem to key to a species, we recommend using a key from an adjacent drainage basin. Periodic updates of checklists for Texas inland fishes will come from previously unreported species, non-native species introductions, extirpations of introduced and native fishes, and multiple species described from a single species through genetic analyses. Sources of this information will be dependent on publications and ichthyological records, such as Texas Natural History Collections (Hendrickson and Cohen 2015). In addition to publications and ichthyological records, an emerging tool for documenting species occurrences is the use of citizen science through web-based applications (e.g., iNaturalist, www.inaturalist.org). We plan to publish revised checklists and keys following the next release of revised common and scientific names list by the AFS-ASIH Committee of Names of Fishes.

II. A PROPOSED FRAMEWORK AND APPLICATION FOR ASSESSING AND REPORTING FISH-ENVIRONMENTAL ASSOCIATIONS

Abstract

Diversity of inland fishes is correlated with many different types of habitat variables. However, there is much variation in how species-environment relationships are reported which reduces the ability to compare data. In this study we propose a framework that resolves three major issues in reporting species-environment relationships: data resolution, terminology, and coverage. To show its utility we then applied the framework on species-environment data that was taken over 15 years by academia, government agencies, and private consulting. The result was environmental associations across 36 categories within 11 habitat variables for 146 inland fish species. Using common terminology, data resolution, and coverage, our standardized and adaptable framework will facilitate communication benefiting research, conservation, and management.

Introduction

“Where there is water, there is fish” – C. L. Hubbs (Matthews, 1998). Organisms are directly and fundamentally linked to their environments (Kearney, 2006). Inland fishes evolved morphologically, physiologically, and behaviorally to occupy almost every aquatic habitat and tend to segregate among available habitats (Hynes, 1970; Keast and Webb, 1966; Lowe-McConnell, 1987; Matthews, 1998). Aquatic environments for fishes include water quality habitat variables, such as temperature, dissolved oxygen, conductivity, and pH (Cech et al., 1990; Craig et al., 2019; Fischer and Paukert, 2008; Winemiller et al., 2008), physical habitat variables, including geomorphic units,

substrates, vegetation, woody debris, cover, depths, and current velocities (Bond and Lake, 2003; Boys and Thoms, 2006; Hayes et al., 1989; Johnson and Jennings, 2004; Leavy and Bonner, 2009; Mueller and Pylon, 2010; Vadas, 1992). Since fishes are related and constrained by their environments, quantifying species-environment relationships are fundamental goals of fish research, conservation, and management (Rosenfeld, 2003). Research linking species-environment patterns to ecological, behavioral, and evolutionary processes (e.g., Armstrong et al., 2013; Schluter and Conte, 2009; Winemiller and Rose, 1992) utilizes species-environment relationships. Conservation of listed threatened and endangered species at the state and federal level requires description, protection, and restorations of aquatic habitats (Bender et al. 2005; Smith et al., 2018). Management of game fishes rely on fish-environment relationships to enhance fisheries (e.g., Swales, 1989). Therefore, fish research, conservation, and management depend on the resolution and accuracy of species-environment relationships. Standardizing how species-environment relationships are quantified and communicated among various studies will facilitate comparability across fish research, conservation, and management.

Quantification of species-environment relationships vary in time, effort, and inference. Studies range from intensive manipulative laboratory studies to rapid field based environmental measures of where individuals were captured (Rosenfeld, 2003). Environmental associations are often reported in species and community studies because of the speed and ease of quantification (Barbour et al., 2003). Several approaches of measuring and reporting environmental associations are available, depending on study objectives (Fisher et al., 2012). Limitations of environmental association studies are not

the data themselves but the lack of comparability with other studies due to data resolution, terminology, and coverage. Firstly, data resolution differs, ranging from qualitative low-resolution environmental association statements that are common in books with compiled species profiles (e.g., Thomas et al. 2007), to semi-quantitative large-scale approaches (e.g., Frimpong and Angermeier, 2009), and quantitative high resolution environmental associations often limited in geographic scope (e.g., Kollaus and Bonner 2012). Second, terminology differs when describing habitats and fish-environment associations. Standardized habitat terminology exists for some variables (e.g., substrate; Blair and McPherson, 1999) but is lacking for others such as depth (e.g., shallow vs. deep). Terminology for fish-environment associations (e.g., riffle specialists; Martin-Smith, 1998) can be expressed using defined categories or guilds that group fishes based on similar use of a resource (Frimpong and Angermeier, 2010). An issue is that category and guild assignments are often made from low resolution, often qualitative data, and rarely are at fine-scale quantification (summary in Austen et al., 1994). When quantitative approaches are used, they often have low power (e.g., low sample size) for accurate and precise inference of a species. Third, coverage (i.e., how representative the sample is of the population) differs, ranging in sample size and scale spatially and temporally. Sample size improves inferences of environmental associations (e.g., Hernandez et al., 2006; Soetaert and Heip, 1990). Also, greater spatial and temporal coverage improves inferences of environmental associations (Aguirre, 2009, Cureton and Broughton, 2014). Assessing and reporting of fish-environment associations under a standardized framework that addresses limitations would improve comparability among fish-environment association estimates.

In this paper we propose a standardized and adaptable framework for assessing and reporting fish-environment associations. The framework is designed to address limitations of data resolution, terminology, and coverage in fish-environment association studies. Data resolution limitation is addressed by providing both quantitative and qualitative (i.e., quantitatively defined) descriptions for fish-environment associations, developing and using consistent terminology for habitat variable categories and fish associations, while compiling data from multiple sources to improve coverage. Herein, we described the individual steps within the framework, that consist of data compilation, categorizing habitat variables, quantifying (i.e., descriptive statistics), and qualifying (i.e., terminologies), fish-environment associations per habitat variable and categories (Figure 2.1). We demonstrated the application of the framework with a database consisting of habitat variables for 146 inland fishes taken from 10 drainages from inland water of Texas and Louisiana collected over 15 years from university, government, and private consulting studies.

Fish-environment association framework

Data compilation

Data compilation consists of delineating the area of interest, searching and obtaining data, concatenating of data into a single database, and selecting habitat variables. Area of interest could include a single drainage, multiple drainages, or drainages within a state jurisdiction boundary. Geographically larger areas of interest are recommended over geographically smaller areas of interest in order to increase coverage. Available fish-environment association data are searchable and may be obtained from publicly available

sources, including published peer-reviewed studies, dissertations, theses, and government and non-government reports. Fish-environmental association data (hereafter “raw data”) typically includes occurrence or abundance estimates per species and per habitat sampled (Doledec and Chessel, 1994); however, studies often summarize the information tables and figures. Raw data are becoming more readily available via requirements to make raw data publicly accessible in most academic journals (e.g., PLOS ONE) and via online open-access databases (e.g., EPA National Aquatic Resource Surveys). If not readily available, access and permission to use raw data from corresponding author can be obtained. Coalescing raw data into a single database requires inspection of the data to ensure compatibility among raw data sets, since species-environment relationships are scale dependent (Chittaro, 2004). Habitats can be delineated and measured from the microhabitat (fine-scale quantitative examination of hydraulic, bottom-topographic variables at multiple locations within mesohabitat units; (Vadas and Orth, 2000) to continental scales (Fisher et al., 2012; Logez et al., 2013). A common scale for fish-environment associations is the geomorphic unit level 3 (e.g., riffle, run pool), which is defined in Hawkins et al., (1993), while using a range of sampling gear (e.g., seining, electrofishing, visual surveys). Therefore, compatibility of data sets is improved if taken at the same scale (e.g., geomorphic unit), although data obtained from smaller scales could be integrated to larger scales. Segregation of samples should be by the habitat, where each geomorphic unit sampled is a row within the raw data, and measured environmental variables and species are the columns. Each row of raw data should contain measurements of habitat variables and counts of individuals by species within that geomorphic unit sample. A database will be formed from the concatenated raw data,

which should be sorted by species for easy calculation. After the database is created, habitat variables should be considered for inclusion if measured in the majority of studies within study area. Habitat variables do not need to be common across all raw data sets but should be common to most of the raw data sets.

Categorizing habitat variables

Habitat variables consist of three types: binomial, proportional, and continuous. Binomial and proportional habitat variable categories are defined before the collection of raw data, using dummy variables (e.g., 0, 1 to denote level 3 geomorphic units; Hawkins et al. 1993), a single category (e.g., percent cover; (Allouche, 2002), or multiple categories with standardized criteria (e.g., substrates; Blair and McPherson 1999). Continuous habitat variables can be categorized after compiling the database by using literature-supported definitions (e.g., specific conductance; Oertli, 1964) or, in the absence of literature-supported definitions for habitat variables like current velocity and water depth, quantile methodologies (Austen et al. 1994). Quantile methodologies use the breadth of the continuous habitat variable and enables the categorization (i.e., number of quantiles) to be determined based on ecologically relevant breaks. For example, three categories of water depth (i.e., shallow, moderate, and deep) might be deemed ecologically relevant and logical per the breadth of water depths measured in the habitat database. Terciles would be used to quantitatively create the three categories: shallow water depth (0 to 33rd percentile of all reported depth measurements), moderate water depths (34th to 66th percentiles), and deep water depths (67th to 100th percentiles).

Quantify and Qualify fish-environment associations per habitat variable and categories.

Steps in the quantification process differ among habitat variables, depending on if the habitat variables are binomial, proportional, or continuous. For binomial habitat variables (e.g., geomorphic unit categories: run, riffle, pools), occurrences of individuals within each category are divided by the total number of occurrences for that species and multiplied by 100. For proportional habitat variables, the central tendency (e.g., mean) is calculated for each habitat variable (e.g., percent cover) or for each habitat variable category (e.g., percent silt). For continuous habitat variables, summary statistics (i.e., mean, standard deviation, minimum, and maximum) are calculated for each habitat variable. To calculate percentages of fish in each continuous habitat variable category, the number of individuals within each habitat variable category are divided by the total number of individuals for that species and multiplied by 100. Mean and standard deviation can be calculated as either weighted (i.e., considering each individual as an independent unit) or unweighted (i.e., each observation or row is an independent unit and individuals of the same species are considered as one). Weighted means and standard deviation use abundances, whereas unweighted means and standard deviations use occurrences to express the fish-environment association. Both can be calculated, and therefore available, depending on the desire to express the fish-environment association based on occurrence or as abundance. Qualification of the quantified habitat variable categories uses a modified version of the ACFOR scale (Stiers et al., 2011, for application see Craig et al., 2017; Faucheux et al., 2019). The acronym ACFOR represents abundance, common, frequent, occasional, and rare, which are qualitative terms often used to express fish-environment associations. Qualitative terms were

assigned to percentages among habitat variable categories: abundance (>75%), common (50 to 74.9%), frequent (25 to 49.9%), occasional (5 to 24.9%), and rare (> 0 to 4.9%).

Application: fish-environment associations of Texas inland fishes

Data compilation

Our area of interest was the inland waters of Texas and western Louisiana (see Craig and Bonner, 2019 for definitions of inland waters and fishes). Raw data were compiled from published literature, agency reports, and unpublished data within 10 river basins of Texas and Louisiana: Canadian, Red, Calcasieu, Sabine/Neches, Trinity, Brazos, Colorado, Guadalupe/San Antonio, Nueces, and Rio Grande/Pecos. Sources of the raw data were obtained from published studies (Bean et al., 2007, Bonner and Wilde 2000, Bonner et al., 2005, Dautreuil et al., 2016, Heard et al., 2012, Kollaus and Bonner 2012), theses and dissertations (Behen 2013, Curtis 2012, Labay 2010, Pfaff 2019, Ruppel 2019, Scanes 2016, and Watson 2006), private consultants (Bio-West, INC.), agency reports (Texas Parks and Wildlife in River Studies 1-27 reports (accessed via <https://tpwd.texas.gov>), and unpublished sampling collections (C. Craig and T. Bonner, unpublished data). Studies were designed primarily to collect juvenile and adult fish from lotic systems across seasons. Raw data also were taken at the geomorphic unit scale, enabling the concatenating of raw data unto a single database, although geomorphic units were sampled using different gear (i.e., seining, backpack electroshocking, boat electroshocking, and SCUBA surveys). We retained all fishes as reported within each study. The majority (85%) of fishes observed had large sample sizes ($N > 20$; Simonson et al., 1994). Few species had single digit counts, such as the Rio Grande Shiner *Notropis*

jemezanus (N = 5), which is ranked low in redundancy, resiliency, and representation in my study area (Faucheux et al., 2019). My rationale for retaining species with low sample sizes is the paucity of environment information available for these species and their status as species of conservation concern. We also retained all habitat information as reported, except for turbidity estimates since turbidity was measured in <50% of the studies. Not all geomorphic units sampled within the database had a full complement of habitat variables available. Missing data remained as blanks in the database.

Categorizing habitat variables

Eleven habitat variables were retained in the database (Table 2.3). Binomial data were used for geomorphic units. Proportional data were used for percent substrates, percent cover, percent vegetation, and percent woody debris. Continuous data were used for dissolved oxygen (mg/l), conductivity ($\mu\text{S}/\text{cm}$), pH, current velocity (m/s), depth (m), and temperature ($^{\circ}\text{C}$). Binomial and proportional habitat variables did not require categorization, since categorization was done in the raw data (Table 2.1). Among continuous habitat variables, we used literature-supported categories for dissolved oxygen, conductivity, and pH measurements. We followed U.S. Environmental Protection Agency (EPA) one-day minimum dissolved oxygen threshold (3.0 mg/L; EPA 1996) to develop two dissolved oxygen categories: hypoxic (< 3.0 mg/l) and oxic (≥ 3.0 mg/l). We followed Oertli (1964) nomenclature to develop four conductivity categories: oligohaline ($< 8,959$ $\mu\text{S}/\text{cm}$), mesohaline (8,959 – 29,158 $\mu\text{S}/\text{cm}$), polyhaline (29,158 – 46,248 $\mu\text{S}/\text{cm}$) and euhaline ($> 46,248$ $\mu\text{S}/\text{cm}$). We followed EPA standards (EPA 1996)

to develop three pH categories: acidic (pH < 5), neutral (pH range: 5 to 9), and basic (pH > 9).

Quantile methodologies were used to develop categories for depth, temperature, and current velocity. Three categories (tercile) for depth and temperature and four categories (quartiles) for current velocity were deemed ecologically relevant and justified per the breadth of each habitat variable (Figure 2.2). Three categories for depth were shallow (≤ 0.3 m), moderate (> 0.3 to 0.7 m), and deep (> 0.7 m). Three categories for temperature were cold ($< 21.5^{\circ}\text{C}$), cool ($21.5 - 25.7^{\circ}\text{C}$), and warm ($> 25.7^{\circ}\text{C}$). Four categories for current velocity were slack (0 to 0.05 m/s), slow ($0.05 - 0.2$ m/s), moderate ($> 0.2 - 0.46$ m/s), and swift (> 0.46 m/s).

Quantify and qualify fish-environment associations per habitat variable and categories

The concatenated database consisted of 723,505 individuals that represent 24 families and 146 species over 10 drainage taken from 23,787 geomorphic units (Table 2.2). The most abundant family was Cyprinidae (N= 537,291), followed by Poeciliidae (N = 60,891), and Centrarchidae (N= 46,902). The most abundant species was *Cyprinella lutrensis* (N= 263,964) followed by *Pimephales vigilax* (N = 83,195) (Appendix 2.1). We quantified weighted mean, ± 1 standard deviation, minimum value, and maximum value per species for six continuous habitat variables (i.e., dissolved oxygen, conductivity, pH, depth, water temperature, and current velocity) and weighted mean for four proportional habitat variables (i.e., percent substrates, consisting of 10 categories, percent cover, percent vegetation, and percent woody debris) (Appendix 2.2 - Appendix 2.10). Example of qualification of the quantified habitat variables are provided in Appendix 2.11.

Discussion

This framework addresses data resolution limitation by providing both quantitative and qualitative descriptions for fish-environment associations, using consistent terminology for habitat variable categories (e.g., slack, swift) and qualitative fish-environment associations (e.g., rare, abundant), while improving coverage by compiling raw data from multiple sources. We then demonstrated the use of this framework for 146 species (>700,000 individuals) of fishes in 10 drainages in Texas and Louisiana. This framework improved fish-environment associations for many species. An example of improved fish-environment associations by addressing limitations in data resolution and terminology is with the widespread River Darter *Percina shumardi*. The River Darter appears to occupy similar habitats throughout its range (Gulf Slope drainages; Gilbert, 1980). However, data resolution and terminology differ among sources. Based on qualitative fish-current velocity association, the River Darter is “primarily found in fair” (Scott and Crossman, 1974), “characteristically found in moderate” (Ross et al., 2003), “most frequently in rather swift” (Trautman, 1981), “predilection for fast” (Robison and Miller, 2004), and “typically associated with swift” (Bonner, 2014) current velocities. Based on semi-quantitative fish-current velocity association, the River Darter ordinal rank is “swiftest” among four categories by Poff and Allan (1995). Based on quantitative fish-current velocity association, mean current velocity for River Darter is 0.44 m/s (Edwards, 1997). In contrast, the framework has each environmental variable, categories within variables, and associations within categories quantitatively and qualitatively defined, in addition to descriptive statistics which unifies terminology and data resolution. Based on our current velocity associations, the River Darter (N = 314; 2

drainages) is found between 0.0 – 1.4 m/s with weighted mean of 0.88 m/s (± 0.27) and abundant (93% occurrence) in swift (>0.46 m/s) current velocities.

An example of improved fish-environment associations by addressing limitation in coverage (i.e., sample size and spatially) is with a Texas endemic: Texas Shiner *Notropis amabilis*. The Texas Shiner's range is comprised of four drainages (Craig and Bonner, 2019), however published quantitative analysis is limited to two tributaries within two drainages with a sample size of 1,283 individuals (Bean et al., 2007; Kollaus and Bonner, 2012). Craig et al. (2017) qualitatively summarized the two quantitative studies by stating “Texas Shiner associates with clear water, pool habitats, and moderate current velocities (0.1 m/s), and sand, gravel, cobble, and bedrock substrates”. In contrast, the framework allows for comparability of the two quantitative studies in addition to other studies, which increased coverage and improved breadth of the fish-environmental association. Our fish-environment associations for the Texas Shiner were calculated from 28,528 individuals to summarize that the fish was common in run (60%) and occasional in pool (26%) habitats, frequent in slack (32%) and slow (35%) current velocities, and is frequent in gravel substrates (26%).

Given that our application included unpublished raw data, a secondary benefit is the quantification of fish-environment associations for species with limited information. An example of this is the Nueces Roundnose Minnow *Dionda serena*, which is globally imperiled and a Species of Greatest Conservation Need (SGCN) by the state of Texas (NatureServe, 2019; Texas Parks and Wildlife, 2012). Previous environment associations are limited to general descriptions (i.e., rocky pools, sometimes runs; often found among filamentous algae; Page and Burr, 1991). Based on our application, Nueces Roundnose

Minnow (N = 2,297) is abundant in runs (78%), common in vegetation (54%), frequent in shallow (41%) and deep (45%) water, common in slack (54%) and slow (42%) water. Nueces Roundnose Minnow is common in cool water (54%), and abundant in oxic, oligohaline, and neutral pH waters.

Limitations of data and framework

Limitations of the raw data and framework are similar to data limitations that exist for studies that measure and report species-environment associations. Specifically, studies measuring environmental associations are constrained by 1) selection of habitat variables, 2) measurement errors, and 3) the assumption that species-environment associations are meaningful (Mitchell, 2005). Inherent biases exist when researchers choose habitat variables to quantify or exclude. Habitat variables are excluded because they are not thought to affect a species or are difficult to measure (Mitchell 2005). In the framework, we were limited to habitat variables that the studies measured. However, the framework allows for an unlimited number of habitat variables and can be easily updated as more habitat variables are included in the raw data such as riverscape variables (e.g., discharge, turbidity; Gradall and Swenson, 1982; Stefferud et al., 2011) and landscape variables (e.g., canopy cover and land use; Bojsen and Barriga, 2002; Roth et al., 1996). Measurements errors in the raw data, and therefore our quantitative and qualitative summary statistics, are in two forms: measuring the habitat variables and measuring populations. Error in measuring habitat variables comes from converting habitat variable, which are inherently continuous, into lower resolution scales. For example, geomorphic unit was used the unit of measure in the raw data, but fishes could be associating with

certain microhabitats within geomorphic units (Grossman and Freeman, 1987; Yeiser and Richter 2015). Error in measuring populations comes from low spatial and temporal coverage, as well as, low sample sizes within a population. In this study, 15% of fish species had low sample sizes (< 20 ; Simonson et al., 1994), yet we decided not to exclude those species because our results provide preliminary environment association data and highlight the need for future study of these species. I assumed that fish-environment associations are meaningful and can be assessed (e.g., Leavy and Bonner, 2009) but requires more effort and time (e.g., conducting experiments to assess fish preferences and requirements; Rosenfeld, 2003). Although preferences and requirements might be unknown, quantifying the fish-environment associations demonstrate that fishes are not homogeneously distributed among aquatic habitats; therefore, fish-environment associations establish hypotheses for future preference and requirement research.

Future uses and directions

Future uses and directions of our standardized and adaptable framework will be benefited by the quality and quantity of fish-environment associations. Future uses of the framework and application include providing the foundation for numerous ecological, evolution, and conservation studies and applications. For example, fish-environment associations with greater quality and quantity of associations will improve upon grouping species into ecologically relevant categories (e.g., Winemiller and Rose, 1992). Likewise, ecological models, such as habitat suitability (e.g., Zorn et al., 2012), and climate change (e.g., Guse et al., 2015), are reliant on high quality and large quantity of fish-environment associations. The framework also identifies gaps in fish-environment associations. In our

area of interest, our concatenated database provided fish-environment associations for 146 species, which is 75% of the inland fishes found in Texas (N=196; Craig and Bonner 2019). Future directions could include prioritizing funding and research for SGCN species in need of fish-environment association quantification. Among 59 SGCN in Texas (Bender et al. 2005), we quantified fish-environment associations for 64% (N = 38) of SGCN; however, 12% (N = 7) of SGCN were among the fishes with low sample sizes. Future uses and directions could also include expanding the framework to other aquatic organisms beyond fish. For example, benthic current velocity would be added as a habitat variable and categories calculated, which would be ecologically relevant for benthic aquatic insects, mussels, and salamanders. Further modifications to environmental variables measured could be made to apply to terrestrial organisms. Regardless of lineage, habitats, and area of interests, quantification and qualification of species-environment associations using common terminology would facilitate communication (Hawkins et al. 1993) benefiting research, conservation, and management.

III. SPRING FLOW LOST: A HISTORICAL AND CONTEMPORARY PERSPECTIVE OF AN URBAN FISH COMMUNITY

Abstract

Water quality and quantity within the upper San Antonio River (Bexar County, Texas) were dominated historically from spring flows of the Edwards Aquifer. Since the 1700s, water quality, quantity, physical aquatic habitats, and presumably fish communities have been altered in the upper San Antonio River, including loss of spring flow and replacement of base flow by treated waste water. The upper San Antonio river fish community provides a unique opportunity to fill gaps in knowledge on spring-associated fish responses to spring flow loss. The purpose of our study was to describe temporal changes in the upper San Antonio River fish community from reported fish collections and infer from reference conditions. Comparisons with reference conditions were necessary since anthropogenic alterations occurred before the first fish collections within the basins. We found the upper San Antonio River fish community changed through time with increases in native and introduced fishes and decreases in spring-associated fish richness and relative abundances. Decreases in spring-associated fish richness and relative abundances were attributed to decreases in spring flow and to changes in water quality; however, specific mechanisms linking loss of spring flow to declines of spring-associated fishes are unknown at this time. Quantifying historical fish community changes through time in systems with a long history of urbanization is difficult, but our assessment provides a greater understanding of the effects of urbanization on spring complexes.

Introduction

Freshwater spring and spring run environments (i.e., spring complexes) are hotspots for biodiversity and endemism (Scarsbrook et al. 2007; Cantonati et al. 2012; Davis et al. 2013), and provide evolutionary refugia for aquatic biota survival and diversification during cycles of glacial and interglacial periods (Tzedakis et al. 2002; Davis et al. 2013). Spring complexes of the karst Edwards Plateau of south central USA are historically and contemporarily habitats for endemic and cosmopolitan flora and fauna (Bowles and Arsuffi 1999). Among fishes, many of the endemic forms are thought to have radiated within the Edwards Plateau (Conner and Suttkus 1986), and some (i.e., spring-associated fishes) have a strong association with water quality (e.g., water temperature) of spring complexes that varies less than the water quality outside of spring complexes (Slade et al. 1986; Hubbs 1995; López-fernández and Winemiller 2005; Kollaus and Bonner 2012). As such, spring-associated fishes have greater relative abundances and densities within spring complexes compared to outside of spring complexes. Within spring complexes, species richness, relative abundance, and densities of spring-associated fishes are positively related to magnitude of spring flow (Craig et al. 2016).

Spring complexes of the Edwards Plateau differ along a gradient of anthropogenic alterations. Non-urbanized and minimally-disturbed spring complexes have intact fish communities, dominated by spring-associated fishes (Watson 2006; Kollaus and Bonner 2012). Urbanized spring complexes have minor changes in fish communities (e.g., increases in introduced fish richness) when spring flows are maintained (Garrett et al. 1992; Kollaus et al. 2015; Scanes 2016). When spring flows are not maintained and the spring complex is dewatered, the fish community is extirpated (e.g., Winemiller and

Anderson 1997). A gap in our understanding of anthropogenic alterations is how spring-associated fishes respond to loss of spring flows without dewatering of the spring complex.

The upper San Antonio River (Bexar County, Texas) is an example of an Edwards Plateau spring complex that, through time, has lost spring flow but has not been dewatered. The Upper San Antonio River forms from springs, which at one time were considered as one of the largest spring complexes within the Edwards Plateau with flows exceeding 4.5 m³/s (G. Eckhardt, San Antonio Water System, San Antonio, TX, 2016 pers. comm.). Since the 1700s, the watershed surrounding the springs and upper San Antonio River has become urbanized. Anthropogenic alterations consisted of changes to stream morphology, water quality, and groundwater supply (Arneson 1921; Brune 1981; Glennon 2004). Median flow was reduced gradually to 0.36 m³/s (USGS gaging station 08178000; 2013 – 2014) with primary source of base flow shifting from spring water to treated waste water from San Antonio Zoo (0.13 m³/s; Miertschin 2006) and City of San Antonio (G. Eckhardt, pers. comm.). Reported changes in the fish community consist of increased occurrences and abundances of introduced species (Barron 1964; Hubbs et al. 1978). Edwards (2001) reported that introduced fishes accounted for 61% of fish species and 62% of the fish biomass. However, the response of the native fish community, including spring-associated fishes, to reduced spring flows is unknown.

Assessment of historical fish collections and comparison of existing fish community to reference conditions are two common methods used to quantify changes in fish communities related to anthropogenic alterations (e.g., Trautman 1981; Karr et al. 1985; Hughes and Noss 1992). Historical fish collections, however, can lack completeness and

breadth (Davis and Simon 1994; Labay et al. 2011) and consist of fishes taken with a variety of gear and effort (Davis and Simon 1994; McManamay and Utz 2014), which compromises compatibility among collections. In the upper San Antonio River, an additional challenge is that fish collections in the 1800s were taken after documented anthropogenic alterations. In streams with incomplete historical fish collections or, like in the San Antonio River, collections taken after stream degradation, reference conditions can be used to provide expectations of historical conditions and enable assessment of community changes associated with anthropogenic alterations (Davis and Simon 1994). Craig et al. (2016) developed predictive models to estimate species richness, relative abundance, and density of spring-associated fishes within Edwards Plateau spring complex based on spring flow magnitude that range from 0.06 to 4.5 m³/s. Predictions of Craig et al. (2016) as reference conditions, combined with quantification of fishes reported in the river, can provide a more comprehensive assessment of fish community changes in the upper San Antonio River.

The purposes of this study were to describe the temporal changes in the upper San Antonio River fish community based on reported fish collections and inferences made from predicted communities. Objectives were to 1) quantify contemporary fish community species richness and relative abundance and spring-associated fish density among four sites in 2013 and 2014, 2) compare fish community species richness, diversity, evenness, and relative abundance between contemporary collections and published and unpublished fish collections taken from 1853 through 2015, and 3) compare spring-associated fish richness, relative abundance, and density from Objective 1 and Objective 2 to reference conditions. Using reference conditions, we estimated that

upper San Antonio River fish community was dominated by spring-associated fishes (i.e., 7 species, 77% in relative abundance, and 1.8 fish/m²) before anthropogenic alterations and at earliest spring flow estimate of 4.5 m³/s. We predicted that observed spring-associated fish richness, relative abundance, and density taken from 1853 through 2015 are less than expected by reference conditions given the history of anthropogenic alterations within the upper San Antonio River. If supported, then the information would provide insight into spring-associated fish responses to reductions of spring flow. We also estimated that the contemporary fish community should be dominated by spring-associated fishes (i.e., 5 species, 57% in relative abundance, and 0.3 fish/m²) despite flows being reduced to 0.36 m³/s. If observed spring-associated fish richness, relative abundance, and density are less than estimated, then the information would provide insight into effects of anthropogenic alterations (e.g., spring flow loss and replacement with treated waste water) independent of water quantity.

Methods

Groundwater of the Edwards Aquifer discharges 4.6 million m³ of water annually (Hamilton et al. 2003) and provides surface waters in six major river basins of Texas (Rio Grande, Nueces River, San Antonio River, Guadalupe River, Colorado River, and Brazos River; Worthington 2003). Perennial portions of the upper San Antonio River historically began within the city of San Antonio at San Antonio Springs (29°28'7.73"N 98°28'2.80"W) and San Pedro Springs (29°26'49.55"N 98°30'5.86"W) (Figure 3.1). Outflows of San Pedro Springs join the San Antonio River about 10 km downstream from San Antonio Springs (Brune 1981). The upper San Antonio River (i.e., USGS

Segment 1911) continues downstream and through the City of San Antonio until merging with the Medina River approximately 30 km downstream. After the confluence, the lower San Antonio River flows into the Guadalupe River before discharging into San Antonio Bay.

Within the upper San Antonio River, largescale anthropogenic alterations began in the early 1700s with the construction of canals and aqueducts to transport water from the river to Spanish missions (Arneson 1921). By the late 1800s, water was contaminated with human waste; waterborne disease was pervasive (Brune 1981). Municipal water wells were drilled and accessed the same groundwater source as the artesian springs (Ewing 2000). As the City of San Antonio expanded rapidly from the 96th largest city in USA in 1880 to 54th by 1910, municipal water well use increased and artesian springs became intermittent by 1897 (Livingston et al. 1936). Additional water wells were drilled and diverted into the upper San Antonio River for the specific purpose of providing base flow to the river and to avoid complete dewatering of the stream channel. By 1918, artesian wells were the primary source of base flows in the river (Livingston et al. 1936). Beginning around 1930, additional artesian wells were drilled in downtown San Antonio for the purpose of single pass air conditioning systems, when after use, water was returned to upper San Antonio River and contributed to base flow (Livingston et al. 1936). Up to 1 m³/s of well water was used and returned daily to the upper San Antonio River (Call 1953). Through time, wells were abandoned or capped, with the last remaining artesian well capped in 2004. In 2000, treated waste water was pumped into the upper reaches to supplement well water base flow. By 2004, base flows were dependent upon treated waste water discharges, although spring outflows from San

Antonio Springs and San Pedro Springs can contribute to base flows briefly following precipitation events. Currently, the upper San Antonio River drainage area (325 km²) is highly urbanized (60% impervious cover, Kreuter et al. 2001; annual growth rate of 2.4% between 1970-2011; Zhao et al. 2016).

Earliest records of flow monitoring by USGS began in 1915 (USGS gage station 08178000) and was continuously monitored with few exceptions from 1938 to 1997. USGS gage station 08178050, located about 3 km downstream, began in 1992 and continuously monitored with few exceptions. Mean daily flow during the shared period of record (1992 – 1997) were correlated ($r^2 = 0.90$) with gage station 8178050 having slightly greater ($< 0.1 \text{ m}^3/\text{s}$) mean daily flow. A composite hydrograph was constructed, using mean daily flows from USGS gage station 08178000 (1915 – 1997) and mean daily flows from USGS gage station 08178050 (1997 – 2015) (Figure 3.2). Median of mean daily flows was $0.74 \text{ m}^3/\text{s}$ from 1915 through 2015. Median of mean daily flows was $0.36 \text{ m}^3/\text{s}$ (range: 0.01 – 5.4) during contemporary fish community collections.

To estimate contemporary community structure, we sampled four sites within the City of San Antonio four times from June 2013 to April 2014. Site 1 (29°27'32.23"N 98°28'25.75"W) was the most upstream site and located 2.5 km downstream from San Antonio Springs. Site 1 was within a forested city park, consisted of run, riffle, and pool mesohabitats, and located downstream from the San Antonio Zoo and city wastewater discharge sites. Site 2 (29°26'26.71"N 98°28'56.62"W) was located near downtown San Antonio and 2.5 km downstream from Site 1. Site 2 was artificially channelized and consisted of run mesohabitat. Site 3 (29°21'52.47"N 98°28'18.68"W) was located within another city park and located 12 km downstream from Site 2. Efforts (San Antonio River

Improvements Project, 2009 – 2012) to create mesohabitats in this area provided riffle, run, and pool habitats, riparian vegetation, and a reconfigured low head dam. Site 4 (29°16'31.55"N 98°26'5.84"W) was located 11 km downstream from Site 3. Site 4 was the least physically altered site (i.e., meandering stream, dense riparian vegetation) with run, pool, and backwater mesohabitats.

Fishes were sampled from available mesohabitats (i.e., riffles, pools, runs, and backwaters; Bain et al. 1999) within 200 to 500 m reach at each site using a combination of multiple single pass seining (3.2 mm mesh), bag seining (3.2 mm mesh), barge electrofishing (Smith-Root Model 2.5 GPP), and backpack electrofishing (Smith-Root Model 12-b POW). Seines were used at each site in slow moving, wadeable habitats, and barge and backpack electrofishing were used near woody debris, in shallow riffle habitats, or in deeper waters. Sampling techniques were standardized by area. All fishes were identified to species (Hubbs et al. 2008) and enumerated. Juvenile species of the genus *Lepomis* <15 mm in total length were grouped due to difficulty in confidently identifying morphologically distinguishing features. Fishes were released except for voucher specimens. Voucher specimens were kept, one per species, at each site and were euthanized with a lethal dose of tricaine methanesulfonate (MS-222) and fixed in a 10% formalin solution. Fishes were taken in accordance with Texas State University Animal Use and Care protocol 1207-0109-01 and Texas Parks and Wildlife Scientific Permit SPR-0601-159. Percent substrates, percent vegetation, percent woody debris, water depth, and current velocity were estimated at each site and by mesohabitat. Water temperature (°C), pH, conductivity (µS/cm), and dissolved oxygen (mg/l) were measured at each site using a YSI-85 multi-probe meter. Species richness (S), relative abundance

(%), diversity (H), and evenness (E) were calculated by combining quarterly samples by site. Diversity was calculated using the Shannon-Wiener index, and evenness was calculated using Shannon's evenness index. Species richness, Shannon-Weiner diversity index ($\log_e$), and evenness ($E = H / H_{\max}$) were calculated by site.

Additional fish community data were obtained for the upper San Antonio River main stem from published and unpublished collections taken between 1853 and 2015.

Collections were grouped by time periods. Fish records from 1853 through 1979 were obtained from museum records (Hendrickson and Cohen 2015), Barron (1964), and Hubbs et al. (1978). Records contained partial reporting of fish collections; therefore, we only retained and combined species occurrences to represent the earliest time period. For the 1980s (1980 – 1989), fish occurrences and counts were obtained from Twidwell (1984) and Gonzales (1988). For the 1990s (1990-1999), fish occurrences and counts were obtained from San Antonio River Authority (1996) and museum records (Hendrickson and Cohen 2015). For the 2000s (2000 – 2009), fish occurrences and counts were obtained from Edwards (2001), Hoover et al. (2004), Gonzales and Moran (2005), BIO-WEST (2012), and Texas Commission on Environmental Quality (2015). For the 2010s (2010 – 2015), fish occurrences and counts were obtained from BIO-WEST (2012), Texas Commission on Environmental Quality (2015), and this study. Species identified among published and unpublished literature were accepted as reported, except for *Pimephales notatus* and *Oreochromis niloticus* (Hoover et al. 2014) since neither species were recorded as vouchered specimens and not previously known from the drainage (Hendrickson and Cohen 2015). Fish names were revised according to Page et al. (2013). Fish occurrences and counts were summed among collections by time

period to calculate relative abundances. Fish sampling, when provided, ranged from one technique (e.g., seining) to multiple techniques (e.g., seining, electrofishing, gill netting, and dip netting) and from one to multiple locations within the upper San Antonio River. Combining fish occurrences and summing collections by time period have limitations, when fishes were sampled for different purposes and by different collectors, techniques, and efforts. We acknowledge, as others (Perkin and Bonner 2011; Kollaus et al. 2015), potential limitations in compiling and interpreting fish community changes through time; however, limitations do not preclude use of these data, because these data, at the very least, are a summary of the fish community reported within the upper San Antonio River.

Fishes were categorized as native or introduced (Hubbs et al. 1978; Edwards 2001; Hubbs et al. 2008). Spring-associated fishes (i.e., *Dionda nigrotaeniata*, *Notropis amabilis*, *Astyanax mexicanus*, *Percina carbonaria*) were defined based on range-wide distributions (Craig et al. 2016). *Astyanax mexicanus* is considered introduced into San Antonio River (Brown 1953), a basin adjacent to their native range. This species was retained as a spring-associated fish, because *A. mexicanus* is native in two drainages within the Edwards Plateau reported by Craig et al. (2016) and are associated with minimally-disturbed spring systems. Other introduced fishes (e.g., *Hypostomus sp.*, *Oreochromis aureus*, *Oreochromis mossambicus*) are associated with spring complexes within the Edwards Plateau. These introduced fishes were not retained as spring-associated fishes because of their certainty as introduced species within the Edwards Plateau. Species richness, relative abundance, Shannon-Weiner diversity index, and Shannon's evenness were calculated for each time period after 1979.

Reference conditions for fish community structure of the upper San Antonio River were obtained from models developed by Craig et al. (2016), which predicted spring-associated fish communities related to spring flow. Models were calculated from six independent and minimally-disturbed spring complexes within the Edwards Plateau and represent expectations of spring complex fish communities (i.e., spring-associated fish richness, relative abundance, and density) with median spring flow. Estimated historical flow (x) of the upper San Antonio River ($4.5 \text{ m}^3/\text{s}$; maximum flow assessed in reference conditions) was used to calculate expected spring-associated fish richness ($y = 0.203(1 - e^{(-3.13x)})$). Expected spring-associated fish relative abundance and density were not calculated, because relative abundances were not available in the earliest time period (1853 – 1979) and densities were not available from additional fish collections. Observed spring-associated fish richness were taken from contemporary (2013 – 2014) and additional (1853 – 2015) fish collections. Median flow ($0.36 \text{ m}^3/\text{s}$) was used to calculate expected spring-associated fish richness ($y = 0.203(1 - e^{(-3.13x)})$), relative abundance ($y = 82.53(1 - e^{(-3.35x)})$), and density ($y = 0.203 + 0.352x$). Observed spring-associated fish richness, relative abundance, and density were taken from contemporary fish collections, combined among the four sites. Differences in species richness, relative abundance, and density between expected and observed were assessed by estimating the probability of the standard residual z-score [$Z_{\text{residual}} = (y_{\text{observed}} - \hat{y}_{\text{expected}}) / \text{SD}_{\text{residual}}$] with $N - 2$ DF. Expected species richness was rounded to a whole number.

Results

A total of 5,806 fishes, representing 10 families and 31 species, was collected among four sites from June 2013 through April 2014 (Table 3.1). The most abundant family was Cyprinidae (55%) followed by Poeciliidae (18%), Centrarchidae (16%), and Cichlidae (8.8%). Two spring-associated fishes (*Astyanax mexicanus* and *Percina carbonaria*) were found within the upper San Antonio River. Spring-associated fishes were most abundant at Site 1 (11.3%) followed by Site 3 (1.8%) and had a combined relative abundance of 1.5% and a combined density of 0.02 fish/m². We caught 10 introduced species. Water temperatures ranged from 12 to 32°C, dissolved oxygen concentrations ranged from 3 to 13 mg/L, and specific conductivities ranged from 406 to 1091 μ S/cm.

A total of 34,326 fishes, representing 13 families and 52 species, was collected from 1953 through 2015 (Table 3.2). The most abundant families were Cyprinidae (range among time periods: 17 - 54%), Poeciliidae (19 - 35%), and Cichlidae (5.5 – 32%). Species richness ranged from 24 species in the 1980s to 41 species in the 2000s, diversity ranged from 1.89 in the 1980s to 2.32 in the 2000s, and evenness ranged from 0.59 in the 2010s to 0.70 in the 1990s. Diversity increased though time from 1.89 in the 1980s to 2.18 in the 2010s, whereas evenness remained similar between the 1980s and the 2010s. Spring-associated fish richness was greatest with three species in the 2000s. Introduced fish richness was greatest ($S = 15$) in the 2000s. Relative abundances of introduced species were 52% in the 1980s and decreased to 17% in the 2010s. Spring-associated fish relative abundances were 21% in the 1980s and decreased to 2.0% in 2010s.

The model of Craig et al. (2016) predicted a species richness of seven spring-associated fishes (95% CI = ± 2.1) at an earliest spring flow estimate of 4.5 m³/s. Among

1853 through 2015 fish collections, observed spring-associated fish richness of four (i.e., *Dionda nigrotaeniata*, *Notropis amabilis*, *Astyanax mexicanus*, and *Percina carbonaria*) was less than expected ($P < 0.01$; Table 3.3). Models predicted a species richness of five spring-associated fishes (95% CI = ± 2.03) with a relative abundance of 57% (95% CI = ± 15.7) and a density of 0.33 fish/m² (95% CI = ± 0.4) at median flow of 0.36 m³/s. Within the contemporary community, observed spring-associated fish richness of two (i.e., *Astyanax mexicanus*, and *Percina carbonaria*) was less than expected ($P < 0.01$), relative abundance of 1.5% was less than expected ($P < 0.01$), and density of 0.02 fish/m² was not different ($P = 0.15$) from expected.

Discussion

Based on assessments of collections taken from 1853 through 2015 and comparing upper San Antonio River fish community to reference conditions, we observed differences in the fish community through time. Since the 1980s, species richness of native fishes increased, species richness of introduced species increased, and spring-associated fish relative abundance decreased. As predicted, spring-associated fish richness among 1853 through 2015 collections was less than the reference condition at historical spring flow of 4.5 m³/s, and spring-associated fish richness and relative abundance of contemporary community (2013 – 2014) were less than reference conditions at reduced spring flow of 0.36 m³/s.

Suburban and urban fish communities differ along a gradient of anthropogenic alteration (Wang et al. 2001; Meyer et al. 2005) ranging in extremes from fish community extirpation (Klein 1979) to less abundance in sensitive fishes (Mitner et al.

2004). Based on our assessment, the upper San Antonio River fish community has changed but maintains native fishes including sensitive fishes. The upper San Antonio River currently supports 28 native fishes including three species (i.e., *Notropis volucellus*, *Noturus gyrinus*, and *Percina carbonaria*) considered as intolerant by Linam et al. (2002) per water quality standards. Detected changes in the fish community were largely consistent with other urbanized streams (i.e., increases in introduced fishes, decreases in sensitive fishes; Walsh et al. 2005) with an exception of increases in native fishes. We found increases in native fishes, which is an uncommon finding but similar to findings of Morgan and Cushman (2005). Morgan and Cushman (2005) attribute increases in native fishes to potential changes in food web structure or habitats that allowed for invasion of opportunistic fishes. We attributed increase in native fishes within the upper San Antonio River through time to increases in sampling effort; however, fish moving into our study reach from downstream reaches is possible based on connectivity to non-urbanized reaches (Pretty et al. 2003) and could be attributed to improvements in upper San Antonio River water quality (Miertschin et al. 2006). However, most studies reviewed by Walsh et al. (2005) reported increases in introduced fishes and loss of sensitive fishes. We found increases in introduced fishes, which is associated with human activities (e.g., aquarium dumps; Marchetti et al. 2006). Likewise, we found decreases in the spring-associated fishes, which we define as the sensitive forms in spring systems.

We attributed decreases in spring-associated fish richness between expected ($S = 7$; reference condition) and observed ($S = 4$; 1853 – 2015 collections) primarily to reductions in flow from $4.5 \text{ m}^3/\text{s}$ to $0.36 \text{ m}^3/\text{s}$. A caveat is our uncertainty on the species

richness of spring-associated fishes within the upper San Antonio River before anthropogenic alterations. However, an estimate of seven spring-associated fishes is reasonable, given that the Guadalupe-San Antonio River drainage supports nine spring-associated fishes (Kollaus et al. 2015, Scanes 2016) and the Medina River, a spring complex tributary of the San Antonio River with a median flow of 1.4 m³/s, supports five spring-associated fishes (Hendrickson and Cohen 2015).

We attributed the difference in spring-associated fish richness, relative abundance, and density between expected ($S = 5$; 57% in relative abundance; 0.33 fish/m² in density; reference conditions) and observed ($S = 2$; 1.5%; 0.02 fish/m²; contemporary community) at 0.36 m³/s, primarily to changes in water quality associated with loss of spring flow. Since the hydrograph record began in 1915, median flows have remained relatively unchanged among time periods (range: 0.36 – 1.95), except that spring flow gradually was reduced and then lost with capping of the last artesian well in 2004. Also, water quality has been impaired before and during the hydrograph record. More recently, the upper San Antonio River has low dissolved oxygen, acute selenium levels, acute and chronic organics levels, and high levels of *E. coli* and fecal coliform (Texas Commission on Environmental Quality 2002). The relationship between the loss of spring flow and the contemporary spring-associated fish community suggests a direct relationship. However, the exact mechanism linking spring-associated fish to spring flow is unknown at this time and more information is needed to understand specific mechanisms. Besides loss of spring flow, other factors could explain decreases in spring-associated fishes, such as legacy effects of >100 years of water quality impairment or a suite of other anthropogenic alterations. Urban systems have synergistic relationships among water quantity, water

quality, and stream morphology; therefore, relating fish community response to a single or few factors is difficult (Meyer et al. 2005; Walsh et al. 2005).

Researchers struggle to quantify historical fish community changes in rivers with a long history of urbanization. Observations of the fish community changes are anecdotal (e.g., River Thames, United Kingdom; Carter and England 2004) or take place long after anthropogenic alterations occur (e.g., Seine River, France; Beslagic et al. 2013). In this study, challenges in quantifying fish community changes included fish records taken after anthropogenic alterations, incomplete records since first fish collections, inferring expected fish communities from reference conditions, and uncertainty in historical flow. Despite the challenges, our analysis of upper San Antonio River fish community can contribute to a greater understanding of urbanization effects on spring complexes. Specifically, we quantified the gap in knowledge of spring-associated fish responses to loss of spring flows without dewatering of the spring complex. With declines and loss of spring flow, spring-associated fishes decline. In contrast, spring complexes are resistant to urbanization when spring flows are maintained (Kollaus et al. 2015). Spring flow, similar to river flow (Poff et al. 1997), is likely the master variable maintaining spring complex fish communities by regulating physical, chemical, and biological processes (Whiting and Stamm 1994; Bowles and Arsuffi 1999). Our study suggests that replacement of spring flows with alternative water sources is not sufficient to maintain the spring-associated fish community because water quality in addition to quantity (Craig et al. 2016) of the spring water influences richness, relative abundance, and density of spring-associated fishes. This is in contrast with the use of treated waste water in non-

spring systems, where relatively small shifts in community structure are observed (Porter and Janz 2003; Brown et al. 2011).

Table 3.1. Upper San Antonio River occurrences and abundances of fishes collected by site from 2013 through 2014. Status identified fishes as native (N) or introduced (I). Asterisk denotes spring-associated species identified by (Craig et al. 2016). Juvenile individuals of the genus *Lepomis* <15 mm in total length were grouped together and not counted towards species richness. Species within genus *Hypostomus* and *Pterygoplichthys* were counted as two species in species richness calculations. Likely each genus contains multiple species, but taxonomic status of species is uncertain (Cook-Hildreth et al. 2016). Diversity was calculated using the Shannon-Wiener index, and evenness was calculated using Shannon evenness.

IV. TESTING EXPECTATIONS OF AN UNDERSTUDIED SPRING FISH COMMUNITY USING MODELS AND HISTORICAL DATA

Abstract

Spring complexes within the Edwards Plateau are unique headwater systems that harbor a unique and endemic spring fish communities. Upper Nueces River basin contains three spring complexes (Nueces, Frio, and Sabinal Rivers) that are understudied. Shifts in the upper Nueces River basin can be documented historically, however, since historical data is limited, models based on reference conditions of other spring complexes can supply additional predictions. The purpose of this study was to test expectations of spring fish community composition using historical data combined with models that provide predictions based on spring flow. No temporal shifts in spring fish community were detected across time periods. Contemporary sampling found species richness, relative abundance, and densities for the Nueces River basin spring complexes met model expectations. Based on the lack of historical changes and model adherence, upper Nueces River basin meets expectations of an intact spring fish community. Results bolster models, which could be used to assess other understudied or unknown spring complex fish communities

Introduction

Fish communities are regulated by a hierarchy of abiotic and biotic structuring mechanisms (Jackson et al., 2001). At a broad level, water quality and water quantity are the coarse filters for community composition (Smith and Powell, 1971). Water quality and quantity change from the headwaters to lower reaches of the river and in turn support

different biotic communities. Lower reaches tend to have more stable diel temperatures as well as greater and more stable water quantity, which supports a diverse biotic community that is more permanent (Vannote et al., 1980). Conversely, headwater streams are defined by their abiotic variability, including fluctuations in temperature. Variable conditions filter the aquatic community such that headwater stream biota is represented by low species richness and transient, often seasonal, inhabitants (Whitney et al. 2016). Known distributional gradients of biota (e.g., River Continuum Concept; Vannote et al., 1980), provide sufficient replication of patterns to inform expectations for previously unstudied streams. Predictive and comparable models, such as Index of Biological Integrity (IBI; Karr, 1991), provide a standardized approach to gauging an understudied stream's health, but selection of appropriate ecological indicators can be difficult, especially in unique systems with many endemic forms (Beyeler, 2001).

Voluminous-discharge karst springs and spring complexes are unique ecosystems and provide a novel exception to headwater community structure through stenoecious abiotic conditions. Karst spring complexes are defined by stable spring discharges that are decoupled from local precipitation and climate (Davis et al., 2013). Spring complexes also offer stenoecious water quality (*e.g.*, stable water temperature, conductivity, dissolved oxygen, low turbidity, and pH). Water quantity and quality of spring complexes provide unique community of spring inhabitants, many of which are endemic to the spring complexes. Spring flow discharge is a primary structuring mechanism of spring complexes that controls secondary structuring mechanisms such as temperature (Craig et al., 2019). Because of this, spring flow discharge is a predictor of spring-associated fish ("spring fish") communities within the Edwards Plateau (Craig et al., 2016). In systems

where spring flow is replaced with flow from a different source, the spring fish community richness, relative abundance, and densities are reduced (Craig and Bonner, In review). However, when spring flow is present, even in a highly urbanized river, the spring fish community remains intact (Kolla et al., 2015). Although understudied, several spring systems exist that harbor unique and endemic biota. In Texas, at least 12 fishes are associated with spring complexes (Craig et al. 2016). Use of traditional monitoring tools poses problems to monitoring spring fish communities due to the complexity of the relationship to spring flow magnitudes, which current biomonitoring methods do not take into account (i.e., Linam et al., 2002). Therefore, predictions made about unstudied or understudied-spring complexes using traditional techniques lack resolution for assessing spring complex community health.

The Nueces river basin (43,300 km²) is an independent river system with minimal land modification (Thomas et al., 2019) and is contained entirely within Texas. Although it is the 6th largest river by drainage area in the state, it has the least studied fish community based on number of museum occurrence records (Hendrickson and Cohen 2015; Table 4.1). Current knowledge exists in species checklists (e.g., Craig and Bonner, 2019), historical museum occurrence records (Hendrickson and Cohen, 2015), and unpublished reports within a small reach (Robertson, 2016). Lack of studies is especially surprising considering the headwaters of the three major tributaries (i.e., Nueces, Frio, and Sabinal) are spring complexes with noted ecologic and evolutionary importance (Hubbs, 1995; Lucas et al., 2009). Assessment of historical fish collections and comparison of existing fish community to reference conditions are two common methods used to quantify unknown fish communities (e.g., Hughes and Noss, 1992; Karr et al.,

1985; Trautman, 1981). Historical fish collections, however, can lack completeness and breadth (Davis and Simon, 1994; Labay et al., 2011) and consist of fishes taken with a variety of gear and effort (Davis and Simon, 1994; McManamay and Utz, 2014), which compromises compatibility among collections. Although historical data are sparse, species occurrences within each tributary could be calculated, which provides insight to historical species presence. Additionally, Craig et al. (2016) predicted spring fish richness, relative abundance, and densities along a spring flow discharge gradient across 6 spring complexes of the Edwards Plateau in Texas. This model could potentially be used in addition to historical occurrence data to predict native spring fish communities based on spring discharge.

The purpose of this study was to assess if three major tributaries (Nueces, Frio, and Sabinal Rivers) of the upper Nueces basin fish communities meet expectations of intact spring complexes using historical data, statistical models, and current sampling. Historical data were compiled from museum records to assess the presence or absence and relative abundance of spring fish community through time. Model predictions from Craig et al (2016) were used to quantify divergence or conformity to other spring complexes of the Edwards Plateau and provide predictions of species richness, relative abundance, and densities based on spring flow discharge. Current fish community will be sampled along a longitudinal gradient of the three major tributaries (Nueces, Frio, and Sabinal Rivers) and were compared to historical and model predictions. Because of minimal urbanization and historically stable spring flows characteristic of Edwards Plateau spring complexes, we predict that the fish communities will have remained

relatively unchanged through time and meet expectations of an intact spring fish community (i.e., the “minimally-altered” category in Craig et al 2016).

Methods

The upper Nueces River basin originates from springs from the Edwards-Trinity Aquifer and includes three main tributaries; the Nueces River, Frio River and Sabinal River that drain approximately 7,000 km². The three tributaries transition from the Edwards Plateau to the South Texas Plains ecoregion around US Highway 90. Once off the plateau, the Sabinal and Frio join about 17 km northwest of Frio Town, Texas (29.103448, -99.443211). The Frio and Sabinal confluence with the Nueces River is 2 km south of Three Rivers, Texas (28.437230, -98.188554), and flows southeast for 115 km where it flows into Corpus Christi Bay in the Gulf of Mexico. For this study, we delineated the upper Nueces River basin as the headwaters to the southern end of the Edwards Plateau (i.e., US highway 90). Historical median discharge is 0.65 m³/s in the Nueces River (period of record: 2009 - 2020; USGS 0818999010), 0.28 m³/s in the Frio River (period of record: 1991 – 2020; USGS 08195000), and 0.06 m³/s in the Sabinal River (period of record: 2014 – 2020; 2014; USGS 08197936).

Historical fish community data was compiled from museum collections from 1851 through 2013 (Hendrickson and Cohen, 2015). The number of individuals by species were grouped by time period. Records from 1851 - 1949 were sporadic and contained partial reporting of fish collections; therefore, we combined these decades to represent the earliest time period. Historical collection reports were not specific to one site and did not provide sufficient individual count information to estimate species relative

abundances until 1950s. Historical collections from 1851-1979 included some presence/absence data which were counted as one individual for analysis. Records taken from 2010 - 2013 before our study were combined with records from 2000s due to limited sampling prior to contemporary sampling.

Contemporary fish community was estimated from 13 sites (Table 4.2) in the upper Nueces River basin (Figure 4.1). Sites were sampled three times between June 2015 and April 2016. At each site, all available mesohabitats (i.e., geomorphic units level 3; Hawkins et al., 1993) were delineated and replicates of each mesohabitats were sampled when available. Within each mesohabitat, fish were taken by a combination of seining and electroshocking. In flowing water mesohabitats (i.e., riffles and shallow runs), downstream boundary of the mesohabitats were blocked with seines and an electroshocker was used, starting at the upstream boundary, to stun the fish and either float downstream into the blocking seine or captured with dip nets. In slack water mesohabitats (i.e., backwaters and pools), common sense seines (3 m x 1.8 m, mesh size = 3.2 mm) and bag seine (5 m x 1.8 m, mesh size = 3.2 mm) were employed in an upstream to downstream direction. In backwaters and pools with large boulders, electroshocker and dipnets were used to sample fish from areas inaccessible with seines. Fishes collected were retained in aerated containers by mesohabitat until after all mesohabitats were sampled. Captured fishes were identified to species (Craig and Bonner, 2019), enumerated, and released excepted for voucher species per site. Voucher specimens were anesthetized in a lethal dose (150 mg/l) of tricaine methanesulfonate (MS-222) and preserved in 10% formalin. Length and width of area sampled were measured for density estimates. Protocols and procedures followed those described in

IACUC 201473646 (issued to T. Bonner) and Texas Parks Texas Parks and Wildlife Department (TPWD) Scientific Permit 0601 – 159 (issued to T. Bonner). Contemporary collections also consisted of fishes taken from four sites on the Frio River in May 2014 with sampling methodologies reported by Robertson (2015).

Among historical and contemporary fish data, richness and relative abundances of spring fishes were calculated. Spring fishes were *Cyprinella lepida*, *Dionda serena*, *Notropis amabilis*, *Astyanax mexicanus*, *Ictalurus lupus*, *Etheostoma lepidum*, and *Percina carbonaria* as defined by Craig et al. (2016). In an effort to detect historical trends in the overall fish community, linear regressions were performed for basin-wide spring fish richness and relative abundance through time. Regressions were also performed for spring fish richness and relative abundance through time for Nueces and Frio tributaries. No regressions were performed for the Sabinal due to lack of samples from 1970 - 2014. In contemporary collections only, densities (the number of individuals taken per species per the area of a mesohabitat) of spring fishes were calculated, because area sampled were not included in historical collections. Observed richness, relative abundances, and densities of spring fishes from contemporary collections were compared to richness, relative abundance, and density model predictions of Craig et al. (2016) for intact spring fish communities per spring flow. Comparisons were made by assessing observed estimates of spring fish richness, relative abundances, and densities from contemporary collections per river with expected estimates (and 95% confidence intervals) of an intact spring fish community. Expected estimates and 95% confidence intervals were calculated for richness ($y = 0.203(1 - e^{(-3.13x)})$), relative abundance ($y = 82.53(1 - e^{(-3.35x)})$), and density ($y = 0.203 + 0.352x$), with x being the median flow per

each river. If observed was not within 95% CI, the difference was interpreted as statistically significant. However, flows in the Sabinal River ($0.06 \text{ m}^3/\text{s}$) were less than those reported in the predictive models. Therefore, we used expected richness, relative abundance, and density from the lowest discharge spring complex (Cypress Creek, $0.065 \text{ m}^3/\text{s}$) in Craig et al. (2016).

Results

The historical and contemporary fish community data within the upper Nueces River Basin consisted of 29,506 individuals, representing 12 families and 46 species, from 1851 - 2016 (Table 4.3). Historical collections (1851 – 2013) within the upper Nueces River basin consisted of 20,878 individuals, representing 12 families and 46 species. The most abundant family was Cyprinidae (66%), followed by Centrarchidae (10%), and Poeciliidae (10%). Spring fish richness was six species within the Nueces River, seven species within Frio River, and five species in the Sabinal River. Mean spring fish relative abundance was 50% in the Nueces River, 40% in the Frio River, and 20% in the Sabinal River. Contemporary collections (2014-2016) within the upper Nueces River basin consisted of 8,628 individuals, representing eight families and 26 species (Table 4.4). The most abundant family was Cyprinidae (67%), followed by Centrarchidae (13%) and Poeciliidae (13%). Spring fish species richness was five species within the Nueces River, six species within the Frio River, and four species within the Sabinal River. Mean spring fish relative abundance was 79% in the Nueces River, 45% in the Frio River, and 14% in the Sabinal River. Spring fish density was $0.69 \text{ fish}/\text{m}^2$ in the Nueces River, $0.18 \text{ fish}/\text{m}^2$ in the Frio River, and $0.35 \text{ fish}/\text{m}^2$ in the Sabinal River.

Across time periods, spring species richness and relative abundance of spring fishes did not differ ($P>0.05$; Table 5) within the entire basin, Nueces River, or the Frio River. Based on historical median spring discharge data and models adapted from Craig et al. (2016), the fish community within the Nueces River ($0.65 \text{ m}^3/\text{s}$ discharge) were predicted to have six spring species, with a relative abundance of 73% spring fish, and a spring fish density of $0.49 \text{ fish}/\text{m}^2$. The fish community within the Frio River ($0.28 \text{ m}^3/\text{s}$ discharge) was predicted to have 4 spring species, with a spring relative abundance of 51%, and a spring fish density of $0.22 \text{ fish}/\text{m}^2$. The fish community within the Sabinal River ($0.06 \text{ m}^3/\text{s}$ discharge) was predicated, based on estimates for lowest discharge (Cypress Creek, $0.065 \text{ m}^3/\text{s}$) in the models, to have 2 spring fishes, with a spring relative abundance of 22%, and a spring fish density of $0.07 \text{ fish}/\text{m}^2$. From contemporary collections, richness, relative abundances, and densities of spring fishes within the Nueces River and Frio River were within predictive models' confidence intervals (Figure 4.2). Spring fish relative abundance and density in the Sabinal River, with median flow less than those reported in the predictive models, appear to fit within the model predictions and 95% confidence intervals. Spring fish richness in the Sabinal River appear to be greater than model predications and 95% confidence intervals.

Discussion

Among contemporary collections, spring fish richness, relative abundances, and densities within the upper Nueces River basin were consistent with model predictions of intact spring fish communities (or appear to be consistent with model predictions as in the Sabinal River). In comparing contemporary spring fishes to historical collections, no

differences were detected through time. However, *Percina carbonaria* were not found in contemporary collections. Only two confirmed records exist of *P. carbonaria*, both in 1970s. Occurrence in the 1970s is surprising, given that there was twice the effort (i.e., fish caught) in the 1950s. Lack of detection prior to and after 1970s could be contributed to the rare nature of *P. carbonaria*. In Faucheux et al., (2019), *P. carbonaria* was found in 6 drainages and 21 reaches within the drainages, however, it was rare (<5% occurrence) in 92% of drainages. Even with the *P. carbonaria* anomaly, upper Nueces river basin supports a diverse spring fish community, which includes two basin endemic fishes (i.e., *Dionda serena* and *Cyprinella lepida*) that occurred in all sampling periods.

Upper Nueces River basin having an intact spring fish community is not surprising given the apparent maintenance of spring flow quantity through the respective USGS gages, and quality through low levels of urbanization (Thomas et al., 2019). Spring complexes within the Edwards Plateau exist on a gradient of degradation which is driven by spring flow quantity and quality. When spring flow quantity and quality is intact, spring fish communities resist the collectively effects of urbanization, non-native introductions, and recreational use (Kollaus et al., 2015). In contrast, when spring flow quantity is altered, such as ceased flows due to excessive groundwater withdraws (Winemiller and Anderson, 1997), it decimates the spring fish community. Without surface water, spring fishes will obviously die unless species can persist in hyporheic zones or in the underground karst system. When spring flow quality is altered in acute changes (i.e., chlorination event; Garrett et al., 1992), or chronic changes (i.e., gradual replacement of spring water with wastewater effluent; Craig and Bonner, In review), spring fish richness, abundances, and densities decrease compared to those in spring

complexes described as intact (Craig et al., 2016). Chronic changes in water quality are more subtle than water quantity changes (i.e., ceased flows) or acute changes (i.e., chlorination event), but can be just as lethal. Water temperature, specifically thermally stable water temperature, is thought to be the key structuring mechanism in maintaining spring fish communities (Hubbs, 1995). Thermally stable water temperature mediates spring fish feeding performance, giving spring fishes competitive advantages over fishes that are not associated with the spring complexes (i.e., riverine fishes) but do have access to them. Craig et al., (2019) provided evidence to support that a spring fish outperforms a closely-related riverine fishes in food consumption (i.e., first feeding, food amount) at spring temperatures, whereas the riverine fish outperforms the spring fish at warmer temperatures.

With changes in spring complex fish communities directly and indirectly tied to spring flow quality and quantity, we demonstrated the application of the Craig et al. (2016) models in assessing the ecological integrity of Edwards Plateau spring fish communities. Adherence with model expectations in conjunction with support of historical records, supports fish communities in the upper Nueces River, Frio River, and Sabinal River are meeting expectations of an intact spring fish community. As such, estimates of richness, abundance, and densities calculated herein can be added to the Craig et al. (2016) models, thereby increasing robustness of the models. The value to updating the Craig et al. (2016) models is that about 200 spring complexes exist in the Edwards Plateau (Brune, 1981), with the majority lacking historical or contemporary collections. Added robustness of the Craig et al. models can improve the reference

conditions of Edwards Plateau spring complexes and have greater ability to assess integrity of these systems.

V. TEMPERATURE-MEDIATED FEEDING BETWEEN SPRING-ASSOCIATED AND RIVERINE-ASSOCIATED CONGENERS, WITH IMPLICATIONS FOR COMMUNITY SEGREGATION

Citation – Craig, C.A., Maikoetter, J.D. and Bonner, T.H., 2019. Temperature-mediated feeding between spring-associated and riverine-associated congeners, with implications for community segregation. Peerj, 6:e6144.

Abstract

Freshwater fish communities segregate along water temperature gradients attributed in part to temperature-mediated physiological processes that affect species fitness. In spring complexes of southwest USA, spring complexes with narrow range of water temperatures are dominated by a community of fishes (i.e., spring-associated fishes), whereas riverine habitats with wide-range of water temperatures are dominated by a different community of fishes (i.e., riverine-associated fishes). The purpose of this study was to test a prediction of the concept that temperature-mediated species performance is a mechanism in maintaining community segregation. We predicted that a spring-associated fish (Largespring Gambusia *Gambusia geiseri*) would feed first and more often in a pairing with a riverine-associated fish (Western Mosquitofish *Gambusia affinis*) at an average spring temperature (23°C) and that the riverine-associated fish would feed first and more often in a pairing with the spring-associated fish at a warm riverine temperature (30°C). Among four trials consisting of 30 pairings at the spring complex temperature (23°C), Largespring Gambusia had a greater number of first feeds (mean $\pm$ 1 SD, 5.0 ± 0.82) than Western Mosquitofish (2.5 ± 1.73) and had greater mean number of total feeds (1.9 ± 0.31) than Western Mosquitofish (0.81 ± 0.70). At the riverine environment

temperature (30°C), Western Mosquitofish had a greater number of first feeds (5.25 ± 1.71) than Largespring Gambusia (2.5 ± 1.73) and had greater mean number of total feeds (2.78 ± 1.05) than Largespring Gambusia (0.94 ± 0.68). Our findings suggest that temperature-mediated species performance could be maintaining segregation between the two fish communities. This study benefits our understanding of distributional patterns and improves threat assessments of stenothermal aquatic organisms.

Introduction

Aquatic species and communities are distributed along altitudinal, geographical, and longitudinal gradients where habitats, food resources, predation, and water quality conditions differ (Vannote et al., 1980; Taniguchi & Nakano, 2000). Among freshwater fishes, water temperature is one of several described mechanisms regulating distributional patterns (Grossman & Freeman, 1987). Temperature can influence interspecific interactions within freshwater fish communities when species temperature tolerances are overlapping (Taniguchi et al., 1998). Temperature-mediated interactions and its influence on species distributions, though difficult to quantify in nature (Gerking, 1994), are supported in laboratory experiments. Taniguchi et al. (1998) and Taniguchi & Nakano (2000) compared water temperature tolerances and behaviors among fishes distributed along an altitudinal gradient and found fish that inhabit cooler water at higher altitudes was more aggressive, consumed more food, had faster growth, and greater survival rate at cooler temperatures than lower altitude fishes. Conversely, fishes, which inhabit warmer water at lower altitudes, were more aggressive, consumed more food, and had faster growth at warmer temperatures than the higher altitude fish. Carmona-Catot,

Magellan & Garcia-Berthou (2013) quantified pairwise feeding performance at three temperatures (i.e., 19, 24, and 29°C) of an introduced warm-water cyprinodont and a native cool-water cyprinodont to assess temperature-mediated interactions in non-native species range expansion and native species extirpation potential. The invasive warm-water cyprinodont had a lower food capture rate compared to the native cool-water cyprinodont at the coolest temperature. At warmer temperatures, the invasive warm-water cyprinodont had a greater food capture rate compared to native cool-water cyprinodont. Laboratory results of temperature-mediated interactions suggest water temperature regulates fish distributions.

Spring complexes within limestone formations of southwest USA are evolutionary refugia with stenoecious water quality, including thermally-constant water temperatures (i.e., stenothermal habitat; range 21.0 - 23.3°C), and distinct fish communities consisting of spring-associated fishes that have greater relative abundances and densities within spring complexes (Craig et al., 2016). As spring complexes transition downstream into riverine environments with less thermally-constant water temperatures (i.e., eurythermal habitat; range: 6 - 30°C) attributed to ambient conditions and merging with higher order streams, relative abundances and densities of spring-associated fishes are reduced and different species of fishes (i.e., riverine-associated fishes) become dominant. Similar to altitudinal gradients (Taniguchi et al., 1998; Taniguchi & Nakano, 2000), water temperature is a suggested mechanism in regulating richness, abundances, and densities of spring-associated fishes and riverine-associated fishes (Hubbs, 1995; Kollaus & Bonner, 2012) with spring-associated fishes being potentially more fit in stenothermal habitats and riverine-associated fishes being potentially more fit in eurythermal habitats.

Dissimilar to altitudinal gradients, spring-associated fishes and riverine-associated fishes do not represent previously researched cold-water and warm-water forms with overlapping tolerances, but both are warm-water forms having similar temperature tolerances (Hagen, 1964; Brandt et al., 1993). And similar reproductive tolerances (Bonner et al., 1998; McDonald et al., 2007). In marine systems, species in stenothermal habitats might select away from eurythermal enzymes and proteins (Graves & Somero, 1982) and select for proteins and enzymes that are more energy efficient within a narrow range of temperatures (Pörtner, Peck & Somero, 2007), whereas species in eurythermal habitats are suggested to conserve temperature-dependent enzymes and proteins that enable tolerance of wide-ranging water temperatures (Somero, Dahlhoff & Lin, 1996). Differences in fitness between spring-associated fishes in stenothermal habitats and riverine-associated fishes in eurythermal habitats could explain patterns in fish community segregation in spring-river systems.

The purpose of this study was to test predictions of the concept that stenothermal habitat of spring complexes is a factor in maintaining community segregation between spring-associated and riverine-associated fishes. The study objective was to quantify feeding (i.e., first feed and number of total feeds) as a measure of performance between spring-associated and riverine-associated fish pairs at two water temperatures and determine if water temperatures favored one species over the other. Water temperatures selected were 23°C, a typical water temperature in spring complexes, and 30°C, a typical summertime temperature in riverine environments. We used two congeneric species, the riverine-associated Western Mosquitofish, *Gambusia affinis* (Fig. 5.1A) and the spring-associated Largespring Gambusia, *Gambusia geiseri* (Fig. 5.1B); Hubbs, Edwards &

Garrett, 2008). Both species have similar thermal tolerances (Hagen, 1964) and mostly abutted distributions in spring-river systems (Watson, 2006; Behen, 2013). If water temperature mediates feeding and therefore potential interactions, we predict *G. geiseri* will eat first and eat more food items than *G. affinis* at 23°C and *G. affinis* will eat first and eat more food items than *G. geiseri* at 30°C. Ability to identify stenothermic aquatic organisms and quantify temperature-mediated segregation will benefit our understanding of distributional patterns and improve threat assessments.

Methods

Laboratory specimens were collected with a seine from the Guadalupe River drainage basin under Texas Parks and Wildlife Scientific Research Permit No. SPR-0601-159. *Gambusia geiseri* were collected from a site (29°53'22.2"N, 97°56'03.7"W) on the San Marcos River. *Gambusia affinis* were collected from a site (29°54'43.8"N, 97°53'50.3"W) on the Blanco River approximately 13 river kilometers away from the *Gambusia geiseri* collection site. Both species were collected from respective sites within the same day. Sexually-mature *Gambusia* >20 mm in total length (TL) (Stevens, 1977; Haynes & Cashner, 1995) were retained. Fishes were transported using insulated 52-L coolers to a laboratory at Texas State University Freeman Aquatic Biology Building within 30 minutes of capture. Within the laboratory, fishes were drip acclimated for 24 h to 23°C with well water from the Edwards Aquifer, which is the same water source as the San Marcos and Blanco rivers (Groeger et al., 1997) and followed approved Texas State University Institutional Animal Care and Use Committee protocol (approval number: 201658034). Fishes were separated by species and placed into 35-L glass aquaria

submersed in a LS-700 Living Stream (Frigid Units, Inc.). Each aquarium was equipped with a sponge filter. The Living Stream utilized a dual feedback heating and cooling system to maintain desired temperature within $\pm 0.5^{\circ}\text{C}$. Photoperiod was 14 h light:10 h dark. To maintain water quality, 50% water changes by volume were completed every 48 h. Fishes were fed high protein BioDiet Grower 1.2 mm (Bio-Oregon) daily *ad libitum*. To avoid any learned feeding behaviors, fishes were fed at varying times throughout the day and various locations of the aquaria. For 23°C feeding trials, food was withheld 24 h prior to feeding trials. For 30°C feeding trials, water temperature was adjusted 1°C per day for 7 d (Carmona-Catot, Magellan & Garcia-Berthou, 2013). Fishes remained at 30°C for 48 h before use in feeding trials, and food withheld 24 h prior to feeding trials. Fishes were kept in the laboratory for a total of three days for the 23°C trial, and ten days for the 30°C trial.

For pairwise feeding trials, one *G. geiseri* and one *G. affinis* were visually size (i.e., within 5 mm) and sex matched (Carmona-Catot, Magellan & Garcia-Berthou, 2013), placed into a 1.25-L opaque container (23 x 15 cm area), and allowed to acclimate for 1 hour. The container was immersed in the Living Stream to maintain the target temperature within $\pm 0.5^{\circ}\text{C}$. Five natural prey items (Order Trichoptera, Family Hydroptilidae; Sokolov & Chvaliova, 1936) were placed into the center of the container using a plastic pipette. The species of the individual feeding (i.e., strikes that consumed all, part, or none of the prey) first was recorded and total feeds were recorded for both individuals. Each pairwise trial was limited to five minutes or until all food items were consumed. After completion, fishes were euthanized in MS-222 (Tricane-S) and preserved in 10% formalin; therefore, a fish was used only once in a feeding trial. For a

no feed trial, the two individuals were given an additional 30 minutes to acclimate and tried for an additional trial. Four independent test batches were conducted at 23°C and 30°C. A test batch was defined as all successful feeding trials at a certain temperature conducted within a 4 – 6 h period. All test batches were conducted between May 2017 and July 2017. Targeted number of pairwise matches was 10 to 11 per batch, but fish jumped out of the container on four occasions, and neither fish eating after 30 minutes occurred on 16 occasions. For both instances, the pairwise trial was ended and recorded observations were discarded.

Number of first feeds and mean number of total feeds were calculated for each species by target temperature. Number of first feeds was calculated by summing the number of first feeds by species per batch. Mean number of total feeds was calculated by summing of total feeds by species in each batch and dividing by the number of pairwise trials. One tailed two sample t-tests (SAS Institute, Cary, North Carolina) were used to detect differences in first feeds and mean number of total feeds between species at 23°C and 30°C. Use of one tailed t-tests were justified by the a priori prediction that the spring-associated fish would outperform at 23°C and the riverine-associated fish would outperform at 30°C.

Results

At 23°C, 30 pairwise first feeds and 82 total feeds were observed out of 150 food items offered between *G. geiseri* and *G. affinis* pairs among four batches. Number of first feeds was greater ($t = 2.61$, $df = 6$, $P = 0.02$) for *G. geiseri* than *G. affinis* (Table 5.1).

Mean number of total feeds was greater ($t = 2.82$, $df = 6$, $P = 0.02$) for *G. geiseri* than *G. affinis*.

At 30°C, 31 pairwise first feeds and 111 total feeds were observed out of 160 food items offered between *G. geiseri* and *G. affinis* pairs among four batches. Number of first feeds was greater ($t = 2.26$, $df = 6$, $P = 0.03$) for *G. affinis* than *G. geiseri*. Mean number of total feeds was greater ($t = 2.94$, $df = 6$, $P = 0.01$) for *G. affinis* than *G. geiseri*.

Discussion

Our predictions that spring-associated *G. geiseri* has greater feeding performance than riverine-associated *G. affinis* at a temperature typical of a spring complex, and conversely, *G. affinis* has greater feeding performance than *G. geiseri* at a temperature typical of a summertime riverine environment were supported by pairwise trials. These results are similar to temperature-mediated feeding performances among families, genera, and species reported by others (De staso & Rahel, 1994; Taniguchi et al., 1998; Taniguchi & Nakano, 2000; Carmona-Catot, Magellan & Garcia-Berthou, 2013). This study, however, is novel in that it documents temperature-mediated performance between a spring-associated fish and a riverine-associated fish with similar thermal tolerances (Hagen 1964). Greater feeding performance of *G. affinis* at a water temperature of 30°C corresponds with the reported fastest growth rates and greatest natality rates of *G. affinis* at 30°C when compared to 20 and 25°C (Vondracek, Wurtsbaugh & Cech, 1988). Our results and the findings of Vondracek Wurtsbaugh & Cech (1988) suggest that a warmer water temperature increases physiological and feeding performance of *G. affinis*, which corresponds with distributions of *G. affinis* during summertime in riverine environments.

Conversely, a water temperature typical of spring complexes increases feeding performance for *G. geiseri*, which corresponds with distributions of *G. geiseri* during summertime in spring complexes. Growth rates, natality rates, and other measures of physiology are not known at this time for *G. geiseri*. Additionally, influences of other abiotic differences between spring systems and riverine systems (e.g., pH, specific conductance, and turbidity; Groeger et al., 1997) have not been assessed as to their role underlying *G. geiseri* and *G. affinis* segregation.

In order to show ubiquity of temperature-mediated performance as a mechanism for segregation among species distributions, feeding comparisons in addition to quantification of other temperature-mediated performance measures (e.g., growth and swimming performance) can be assessed for several other closely related taxa with similar distributions as *G. geiseri* and *G. affinis* within spring-river systems, such as spring-associated *Etheostoma lepidum* (Hubbs, 1985) and riverine-associated *E. spectabile*, *E. fonticola* (Bonner & McDonald, 2005) and *E. proeliare*, *Cyprinella proserpina* (Hubbs, 1995) and *C. lutrensis*, *Dionda argentosa* (Garrett, Hubbs & Edwards, 2002) and *D. diaboli*, and *Ictalurus lupus* (Sublette, Hatch & Sublette, 1990) and *I. punctatus*. In addition, spring-associated fishes and riverine-associated fishes maintain segregation during the winter when water temperatures of riverine environments are colder than water temperatures of spring complexes (Kollaus & Bonner, 2012). Assessments of feeding performance among spring-associated fishes and riverine-associated fishes at typical winter time temperatures would complete the range of conditions in which segregation is maintained. Ultimately, quantification of genetic, physiological, and biochemical mechanisms will be necessary to describe underlying

temperature-mediated performance of spring-associated and riverine-associated species (see review in Somero, Dahlhoff & Lin, 1996). At a minimum, known mechanisms for stenotherm radiation and maintenance can serve as a basis for understanding evolutionary origins and maintenance of segregation among spring-associated and riverine-associated fishes.

Ability to identify stenothermic aquatic organisms and to quantify temperature-mediated segregation will benefit our understanding of distributional patterns and improve threat assessments. Stenothermic organisms are potentially more sensitive to temperature changes related to physical habitat alterations and global climate change than eurythermic organisms because of the lack of gene product selection associated with eurythermic organisms (Somero, Dahlhoff & Lin, 1996). Physical habitat alterations include instream or riparian modifications that manipulate the energy budget or thermal capacity of the surface water (Poole & Berman, 2001), such as discharge of heated effluents (Langford, 1990; Olden & Rahel, 2008), removal of riparian vegetation (Moore, Spittlehouse & Story, 2005), stream channel modification (Nelson & Palmer, 2007), dams and diversions (Olden & Naiman, 2010), and reduction of discharge through groundwater pumping (Sinokrot & Gulliver, 2000). Groundwater sources supporting spring complexes of southwest USA are commodities (Loaiciga, 2003), and groundwater harvest is linked to the loss of spring complexes and associated biota (Craig & Bonner, unpublished data ; Winemiller & Anderson, 1997). Within the Edwards Plateau, there are eight federally listed and 12 Texas state listed fishes that are associated with spring complexes. Our manuscript supports why spring-associated fishes are found within spring complexes, which informs natural resource managers in supervising species and

their habitats (e.g., minimize groundwater withdrawals during periods of natural low flow periods to maintain stenothermal habitats for the spring fishes). Continued climate change in North America is predicted to alter stream flow patterns, increasing storm events, decreased dissolved oxygen, and increases in groundwater temperatures (Poff, Brinson & Day, 2002; Ficke, Myrick & Hansen, 2007). As with physical habitat alterations, stenothermic aquatic organisms are predicted to follow isoclines of suitable habitat (Ficke, Myrick & Hansen, 2007), remain in place and wait for better times, adapt to changes, or become extinct (Clarke, 1996).

Conclusions

This study supports a prediction that temperature mediates species distribution of a spring-associated and a riverine-associated fish through laboratory trials. Novel results of this study show temperature-mediated feeding performance of two species with similar temperature tolerances that inhabit spring-river systems. Although further work is needed to test for the ubiquity among other fishes, this study suggests temperature to be a structuring mechanism for organisms in spring-river systems.

Table 5.1. Number of first feeds and mean number of total feeds by batch for *Gambusia geiseri* and *Gambusia affinis* at 23 and 30°C.

Temperature (°C)	Batch	N of pairs	Number of first feeds		Mean number of total feeds	
			<i>G. geiseri</i>	<i>G. affinis</i>	<i>G. geiseri</i>	<i>G. affinis</i>

BRAZOS RIVER BASIN

KEY TO THE FAMILIES

- 1a. Both eyes on one side of head; without right pectoral fin.. American Soles – Achiridae
- 1b. One eye on either side of head; with both pectoral fins.....2
- 2a. (1b) Body long and slender; without pelvic fins Freshwater Eels – Anguillidae
- 2b. (1b) Body truncated or elongated; with pelvic fins 3
- 3a. (2b) Caudal fin heterocercal or abbreviated heterocercal4
- 3b. (2b) Caudal fin homocercal5
- 4a. (3a) Body covered with ganoid scales; snout formed into a beak; without gular plate..... Gars – Lepisosteidae
- 4b. (3a) Body covered with cycloid scales, snout not formed into a beak, with a gular plate.....Bowfin – Amiidae
- 5a. (3b) Jaws duckbilled Pickerels – Esocidae
- 5b. (3b) Jaws not duckbilled6
- 6a. (5b) One dorsal fin; pelvic fins without uniserial spines7
- 6b. (5b) One or two dorsal fins; pelvic fins with uniserial spines15
- 7a. (6a) With adipose fin.....8
- 7b. (6a) Without adipose fin10
- 8a. (7a) Without barbels.....9
- 8b. (7a) With barbels..... Bullhead Catfishes – Ictaluridae
- 9a. (8a) Scales large, < 50 lateral line scales; incisor teeth present.Tetras – Characidae
- 9b. (8a) Scales small, > 60 lateral line scales; incisor teeth absent Trout – Salmonidae

10a. (7b) Long anal fin with ≥ 17 fin rays	Shads – Clupeidae
10b. (7b) Short anal fin with ≤ 13 rays	11
11a. (10b) Caudal fin forked or emarginated; lateral line usually present.....	12
11b. (10b) Caudal fin truncated or rounded; lateral line usually absent	13
12a. (11a) Inferior, fleshy mouth modified for sucking; > 7 pharyngeal teeth in main row, usually ≥ 10 dorsal fin rays	Suckers – Catostomidae
12b. (11a) Mouth usually not fleshy or modified for sucking; < 7 pharyngeal teeth in main row, usually ≤ 10 dorsal fin rays.....	Minnows – Cyprinidae
13a. (11b) Mature males with rounded anal fin; males and females with 3rd anal fin ray branched, no gonopodium present	14
13b. (11b) Mature males with pointed anal fin forming a gonopodium; males and females with 3rd anal fin ray unbranched	Livebearers – Poeciliidae
14a. (13a) Body robust; teeth in single row are incisor-like and tricuspid (three points on a tooth)	Pupfishes – Cyprinodontidae
14b. (13a) Body elongate; conical (cone-shaped) pointed teeth in a single row or several rows.....	Killifishes – Fundulidae
15a. (6b) Anus anterior to pelvic fins; > 5 soft rays on each pelvic fin.....	Pirate Perch – Aphredoderidae
15b. (6b) Anus posterior to pelvic fins; 5 soft rays on pelvic fins.....	16
16a. (15b) Pelvic fin position abdominal or sub-thoracic; dorsal fins widely separated...	17
16b. (15b) Pelvic fin position thoracic; dorsal fins joined or, if separate, closely adjacent to one another.....	18
17a. (16a) Dorsal fin with 4 thick spines; anal fin with 2-3 spines; adipose eyelids present	Mullets – Mugilidae
17b. (16a) Dorsal fin with 4 to 8 thin spines; anal fin with 1 spine; adipose eyelids absent	Silversides – Atherinopsidae

18a. (16b) One nostril (nare) on each side of head; lateral line interrupted	
.....Cichlids – Cichlidae	
18b. (16b) Two nostrils (nares) on each side of head; lateral line complete, incomplete, or absent	19
19a. (18b) Dorsal fin with > 23 fin rays; lateral line extends to tip of caudal fin.....	
..... Drums – Sciaenidae	
19b. (18b) Dorsal fin with < 23 fin rays; lateral line, if present, does not extend to tip of caudal fin.....	20
20a. (19b) Anal fin with 1 to 2 spines.....	Perches – Percidae
20b. (19b) Anal fin with 3 to 8 spines	21
21a. (20b) Posterior margin of operculum with a sharp spine; spiny and soft dorsal fin separate or only slightly connected; pseudobranchium present and exposed.....	
..... Temperate Basses – Moronidae	
21b. (20b) Posterior margin of operculum without a sharp spine; spiny and soft dorsal fins connected or with deep notch; pseudobranchium covered or absent.....	22
22a. (21b) Lateral line present or incomplete	Sunfishes – Centrarchidae
22b. (21b) Lateral line absent	Pygmy Sunfishes – Elasmobranchidae

KEY TO THE SPECIES

FAMILY LEPISOSTEIDAE—gars

- 1a. Large teeth in upper jaw in parallel rows on each side *Atractosteus spatula*
- 1b. Large teeth in upper jaw in one row, although another non-parallel row might be present 2
- 2a. (1b) Beak long and narrow, least width goes about 12 to 20 times in length; width of beak at nostrils < eye diameter; snout > $\frac{2}{3}$ of head length *Lepisosteus osseus*
- 2b. (1b) Beak short and blunt, least width goes about 5 to 7 times in length; width of beak at nostrils > eye diameter; snout < $\frac{2}{3}$ of head length *Lepisosteus oculatus*

FAMILY AMIIDAE—bowfins

Amia calva

FAMILY ANGUILLIDAE—freshwater eels

Anguilla rostrata

FAMILY CLUPEIDAE—herrings

- 1a. Twenty-nine to 33 anal fin rays; mouth subterminal and below level of middle of eye; black; shoulder spot $\geq$ pupil of eye *Dorosoma cepedianum*
- 1b. Twenty-four to 28 anal fin rays; mouth terminal and at level of eye; black shoulder spot < pupil of eye *Dorosoma petenense*

FAMILY CYPRINIDAE - minnows

- 1a. More than 15 soft rays on dorsal fin; dorsal and anal fins each with a strong serrated spine 2
- 1b. Fewer than 10 soft rays on dorsal fin; dorsal and anal fins without spine 3
- 2a. (1a) Upper jaw with two pairs of barbels *Cyprinus carpio*
- 2b. (1a) Upper jaw without barbels *Carassius auratus*

3a. (1b) Anal fin near caudal fin, distance from snout to origin of anal fin is > 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth with prominent parallel grooves	<i>Ctenopharyngodon idella</i>
3b. (1b) Anal fin not noticeably near caudal fin: distance from snout to origin of anal fin is < 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth without prominent parallel grooves	4
4a. (3b) Intestine wound spirally around swim bladder; keratinous ridge on lower jaw	<i>Campostoma anomalum</i>
4b. (3b) Intestine not wound spirally around swim bladder; keratinous ridge of lower jaw hardly evident.....	5
5a. (4b) Abdomen behind pelvic fins with a fleshy keel lacking scales; lateral line greatly decurved, distance between anterior lateral line scale and ventral most lateral line scale is > 3 scales in height.....	<i>Notemigonus crysoleucas</i>
5b. (4b) Abdomen behind pelvic fin with scales; lateral line not greatly decurved, lateral line descends < 3 scales ventrally from highest point	6
6a. (5b) With maxillary barbels, might be small and not observable without opening the mouth or with magnification.....	7
6b. (5b) Without maxillary barbels	9
7a. (6a) Mouth terminal; distinct black spot located anteriorly on dorsal fin; pharyngeal teeth on main row 5-4 or 5-5.....	<i>Semotilus atromaculatus</i>
7b. (6a) Mouth subterminal or inferior; no distinct black spot on dorsal fin; pharyngeal teeth on main row 4-4	8
8a. (7b) Body silvery, without scattered black specks.....	<i>Macrhybopsis storeriana</i>
8b. (7b) Body with scattered black specks.....	<i>Macrhybopsis hyostoma</i>
9a. (6b) Predorsal scales appear crowded, smaller than scales on lateral body or appear as overlapping scales; black spot in the middle, anterior portion of the dorsal fin	10
9b. (6b) Predorsal scales not crowded; without black spot in the middle, anterior portion of the dorsal fin	11

10a. (9a) Caudal spot, if distinct, continuous with mid-lateral stripe; lateral line incomplete; intestine long, more than twice the standard length.....	<i>Pimephales promelas</i>
10b. (9a) Caudal spot distinct from mid-lateral stripe; lateral line complete, intestine forming a short S-shaped loop	<i>Pimephales vigilax</i>
11a. (9b) Long intestine in a flat coil.....	12
11b. (9b) Short S-shaped intestine	13
12a. (11a) Head width greater than distance from tip of snout to posterior margin of orbital; internal posterior basioccipital process is narrow and peg-like, width of internal posterior basioccipital process fits in to head width at occipital > 7 times.....	<i>Hybognathus placitus</i>
12b. (11a) Head width about equal to distance from tip of snout to posterior margin of orbital; internal posterior basioccipital process is wide and flat, width of internal posterior basioccipital process fits in to head width at occipital < 7 times.....	<i>Hybognathus nuchalis</i>
13a. (11b) Moderately decurved lateral line; diamond-shaped scales; dark shoulder patch present; melanophores concentrated between rays of dorsal and anal fins	14
13b. (11b) Lateral line incomplete, complete-straight, or complete-slightly decurved; scales not noticeably diamond-shaped; without dark shoulder patch; melanophores concentrated along rays of dorsal and anal fins	15
14a. (13a) Caudal fin base with a large black spot, about size of eye	<i>Cyprinella venusta</i>
14b. (13a) Caudal fin base without a large black spot.....	<i>Cyprinella lutrensis</i>
15a. (13b) Distinct and separate black dash at base of dorsal fin; apparent when viewed from above; pharyngeal teeth count usually 0,4-4,0.....	16
15b. (13b) No distinct and separate black dash at base of dorsal fin; pharyngeal teeth count usually 1,4-4,1 or 2,4-4,2	19
16a. (15a) Lateral line scales markedly elevated (taller than wide) anteriorly, elevated scale height 2 to 5 times scale width.....	17
16b. (15a) Lateral line scales not markedly elevated anteriorly, scale height 1 to 2 times scale width	18

17a. (16a) Dorsal and lateral body with melanophores outlining scales; with pronounced black lateral stripe; dorsal fin height goes 2.1 or more times in pre-dorsal length; infraorbital canal complete	<i>Notropis volucellus</i>
17b. (16a) Dorsal and lateral body with sparse melanophores; scales outlined with melanophores are rare; pre-dorsal black spot is prominent and distinct from mid-dorsal stripe; dorsal fin height goes 2.0 or fewer times in pre-dorsal length; infraorbital canal incomplete	<i>Notropis buchanani</i>
18a. (16b) Eye large, eye diameter is > snout length.....	<i>Notropis stramineus</i>
18b. (16b) Eye small, eye diameter is < snout length	<i>Notropis buccula</i>
19a. (15b) Depressed dorsal fin longer than head.....	<i>Hybopsis amnis</i>
19b. (15b) Depressed dorsal fin shorter than head	20
20a. (19b) Mouth is sub-terminal; pharyngeal teeth are 0,4-4,0.....	<i>Notropis atrocaudalis</i>
20b. (19b) Mouth is terminal; pharyngeal teeth are 1,4-4,1 or 2,4-4,2 or 5-5	21
21a. (20b) Dorsal fin origin opposite or anterior to pelvic fin origin	22
21b. (20b) Dorsal fin origin posterior to pelvic fin origin	25
22a. (21a) Prominent mid-lateral stripe; extending through eye	23
22b. (21a) No prominent mid-lateral stripe present.....	24
23a. (22a) Pharyngeal teeth 5-5; mouth small and almost vertical.....	<i>Opsopoeodus emiliae</i>
23b. (22a) Pharyngeal teeth are 1,4-4,1 or 2,4-4,2; mouth large and oblique	<i>Notropis texanus</i>
24a. (22b) Usually 8 anal fin rays; head is narrow, depth at occiput more than width at occiput	<i>Notropis shumardi</i>
24b. (22b) Usually 7 anal fin rays; head is wide, depth at occiput less than or equal to width at occiput.....	<i>Notropis potteri</i>

- 25a. (21b) Small scales, ≥ 41 lateral line scales, > 25 predorsal scales.... *Lythrurus fumeus*
 25b. (21b) Moderate-sized scales, ≤ 40 lateral line scales, < 24 predorsal scales
 *Notropis oxyrhynchus*

FAMILY CATOSTOMIDAE—suckers

- 1a. Dorsal fin long, base $>$ than $\frac{1}{3}$ of standard length; 22 to 30 dorsal fin rays2
 1b. Dorsal fin short, base $<$ than $\frac{1}{4}$ of standard length; 4 to 18 dorsal fin rays5
- 2a. (1a) Small scales, lateral line scales > 50 ; eye closer to back of head than to tip of snout; head abruptly more slender than body; papillose lips..... *Cycleptus elongatus*
 2b. (1a) Large scales, lateral line scales < 45 ; eye closer to tip of snout than back of head; plicate lips3
- 3a. (2b) Subopercle triangular, broadest toward base; knob present at tip of lower lip; blunt snout, forming level with eye *Carpiodes carpio*
 3b. (2b) Subopercle semicircular, broadest towards middle; knob absent at tip of lower lip; rounded snout, forming below level of eye4
- 4a. (3b) Body elongate and slender, greatest body depth goes 2.6 to 3.3 times in standard length, and height of anterior rays in dorsal and anal fins often less than $\frac{2}{3}$ head length in individuals > 300 mm; small eye, eye diameter goes ≥ 2 times in snout length of individuals < 300 mm *Ictiobus niger*
 4b. (3b) Body deep and narrow, greatest body depth goes 2.2 to 2.8 times in standard length, and height of anterior dorsal and anal fin rays often greater than $\frac{2}{3}$ head length in individuals > 300 mm; large eye, eye diameter goes ≤ 2 times in snout length of individuals < 300 mm *Ictiobus bubalus*
- 5a. (1b) Lateral line complete and well developed; air bladder with 3 chambers *Moxostoma congestum*
 5b. (1b) Lateral line incomplete or absent; air bladder with 2 chambers6
- 6a. (5b) Lateral line incomplete; rows of spots..... *Minytrema melanops*
 6b. (5b) Lateral line absent7

- 7a. (6b) Scales larger, lateral scale count 34 to 37; eye larger, eye length $\frac{1}{2}$ of snout length; dorsal fin rays 11 or 12; back with crescentic scale marks.....*Erimyzon sucetta*
- 7b. (6b) Scales smaller, lateral scale count 39 to 43; eye smaller, eye length $< \frac{1}{2}$ of snout length; dorsal fin rays 9 or 10; back without crescentic scale marks.. *Erimyzon claviformis*

FAMILY CHARACIDAE—characins

Astyanax mexicanus

FAMILY ICTALURIDAE—bullhead catfishes

- 1a. Adipose fin joined to the caudal fin or separated by a shallow notch.....2
- 1b. Adipose fin free at tip, not joined to caudal fin3
- 2a. (1a) Mouth terminal; pectoral fin spine not serrated; lower lip and chin not heavily speckled with black pigment.....*Noturus gyrinus*
- 2b. (1a) Mouth sub-terminal; pectoral spine serrated; lower lip and chin heavily speckled with black pigment.....*Noturus nocturnus*
- 3a. (1b) Head dorso-ventrally compressed; mouth terminal to superior . *Pylodictis olivaris*
- 3b. (1b) Head rounded; mouth subterminal4
- 4a. (3b) Caudal fin rounded or shallowly emarginate.....5
- 4b. (3b) Caudal fin deeply forked6
- 5a. (4a) Chin barbels completely or partially black; anal fin rays 17 to 24; anal fin broadly rounded*Ameiurus melas*
- 5b. (4a) Chin barbels white or yellow; anal fin rays 24 to 27; margin of anal fin generally straight..... *Ameiurus natalis*
- 6a. (4b) Anal fin rays 30 to 36; anal fin free margin is straight; medial keel-like ridge anterior to dorsal fin forms humped back appearance*Ictalurus furcatus*
- 6b. (4b) Anal fin rays 22 to 29; anal fin free margin is rounded; no humped back appearance.....*Ictalurus punctatus*

FAMILY SALMONIDAE—salmons

Oncorhynchus mykiss

FAMILY ESOCIDAE—pikes and pickerels

Esox americanus

FAMILY APHREDODERIDAE—pirate perch

Aphredoderus sayanus

FAMILY MUGILIDAE—mullet

1a. Lower jaw rounded, without a symphyseal knob; lower limb of 1st gill arch with 17 to 20 gill rakers; no adipose eyelid; scales ctenoid *Agonostomus monticola*

1b. Lower jaw angular, with a prominent symphyseal knob; lower limb of 1st gill arch with 25 to 60 gill rakers; adipose eyelid well developed in adults; scales cycloid in young, ctenoid in adults *Mugil cephalus*

FAMILY ATHERINOPSIDAE—New World silversides

1a. Scales small, > 60 scales in lateral series, jaws produced into a short beak; snout length > eye length; > 20 anal fin rays *Labidesthes sicculus*

1b. Scales large, < 50 scales in lateral series; jaws not produced into a beak; snout length ≤ eye length; < 20 anal fin rays *Menidia audens*

FAMILY FUNDULIDAE—topminnows

1a. More than 40 longitudinal scale rows; dark vertical barring; gill slit not extending dorsal to uppermost pectoral fin ray *Fundulus zebrinus*

1b. Fewer than 40 longitudinal scale rows; gill slit extending dorsal to uppermost pectoral fin ray 2

2a. (1b) Body with a distinct black lateral band 3

2b. (1b) Body without a distinct black lateral band 4

3a. (2a) Distinct black spots on anterior dorso-lateral region are as pronounced as lateral stripe; distinct black spots throughout dorsal and caudal fins *Fundulus olivaceus*

3b. (2a) Faint black spots on anterior dorso-lateral region are not as pronounced as lateral stripe; distinct black spots near base of dorsal and caudal fins *Fundulus notatus*

- 4a. (2b) Dorsal fin originating anterior to anal fin origin; more than 15 scale rows from pelvic fin origin to isthmus predorsal stripe absent or not reaching occiput
..... *Fundulus grandis*
- 4b. (2b) Dorsal fin originating posterior to anal fin origin5
- 5a. (4b) Red to dark spots in multiple rows longitudinally along lateral sides; usually with dark subocular bar*Fundulus blairae*
- 5b. (4b) Body mottled, barred or irregularly spotted; no dark subocular bar
..... *Fundulus chrysotus*

FAMILY CYPRINODONTIDAE—pupfishes

- 1a. Abdomen with scales anterior to pelvic fins; distance from origin of dorsal fin to end of hypural plate > distance from origin of dorsal to anterior nostril.....
.....*Cyprinodon variegatus*
- 1b. Abdomen without scales anterior to pelvic fins; distance from origin of dorsal fin to end of hypural plate < the distance from origin of dorsal to anterior nostril
..... *Cyprinodon rubrofluvialis*

FAMILY POECILIIDAE—livebearers

- 1a. Origin of dorsal fin anterior to anal fin origin; intestinal canal long with many convolutions.....*Poecilia latipinna*
- 1b. Origin of dorsal fin posterior to anal fin origin; intestinal canal short with few convolutions..... *Gambusia affinis*

FAMILY MORONIDAE—temperate basses

- 1a. Body depth goes < 3 times in standard length; teeth in single patch on back of tongue.....*Morone chrysops*
- 2b. Body depth goes > 3 times in standard length; teeth in 2 parallel patches on back of tongue*Morone saxatilis*

FAMILY CENTRARCHIDAE—sunfishes

- 1a. Five to 8 anal spines2
- 1b. Three anal spines.....3

2a. (1a) Dorsal fin set back on body, length of dorsal fin base < distance from its origin to posterior margin of eye; lateral body with wide to narrow dorsal black bands; ≤ 6 dorsal spines.....	<i>Pomoxis annularis</i>
2b. (1a) Dorsal fin set forward on body, length of dorsal fin base equal to or greater than distance from its origin to posterior margin of eye; lateral body with checkerboard black and light pattern; ≥7 dorsal spines	<i>Pomoxis nigromaculatus</i>
3a. (1b) Body slender, body depth contained > 3 times into standard length.....	4
3b. (1b) Body deep, body depth contained < 3 times into standard length.....	7
4a. (3a) Dorsal fins narrowly joined at base, forming a deep notch; upper jaw extends past posterior margin of eye in adults; mid-lateral stripe generally complete, rows of spots ventral to mid-lateral stripe faint and incomplete	<i>Micropterus salmoides</i>
4b. (3a) Dorsal fins broadly joined at base forming a shallow notch; upper jaw does not reach past posterior portion of eye; bases of soft dorsal and anal fins scaled	5
5a. (4b) No tooth patch on tongue; lower lateral region scales without black spots forming horizontal rows.....	<i>Micropterus dolomieu</i>
5b. (4b) Tooth patch on tongue; lower lateral region scales with black spots forming horizontal rows.....	6
6a. (5b) Mid-lateral stripe often appears interrupted anteriorly, rows of spots ventral to mid-lateral stripe distinct and complete.	<i>Micropterus punctulatus</i>
6b. (5b) Dark wide midlateral stripe present and disconnected anteriorly into a narrow midlateral stripe posteriorly, forming vertical bars.....	<i>Micropterus treculii</i>
7a. (3b) Teeth on tongue; head and opercle with 3 to 5 distinct dark and light longitudinal stripes; red spot on posterior margin of opercle flap in fresh specimens....	<i>Lepomis gulosus</i>
7b. (3b) No teeth on tongue; head and opercle lacking distinct dark and light longitudinal stripe.....	8
8a. (7b) Pectoral fins long and pointed, reach anterior portion of eye or beyond when bent forward.....	9
8b. (7b) Pectoral fins short and rounded, do not reach past eye when bent forward.....	11

9a. (8a) Opercle flap stiff to its margin, posterior margin either red or orange in live specimens	<i>Lepomis microlophus</i>
9b. (8a) Opercle flap flexible, posterior margin not red or orange in live specimens	10
10a. (9b) Opercle flap black to the margin; black spot on posterior base of soft dorsal fin	<i>Lepomis macrochirus</i>
10b. (9b) Opercle flap outlined with thick white band; lacking black spot on posterior base of soft dorsal fin.....	<i>Lepomis humilis</i>
11a. (8b) Black opercle flap stiff near the posterior margin with bone supporting all or majority of the flap.....	12
11b. (8b) Black opercle flap flexible near the posterior margin without bone supporting majority of the flap.....	14
12a. (11a) Lateral line incomplete; smaller individuals with black spot surrounded by white margin on posterior base of soft dorsal fin	<i>Lepomis symmetricus</i>
12b. (11a) Lateral line complete; black spot, if present, on posterior base of soft dorsal fin without white margin	13
13a. (12b) Body elongated with black spot on posterior base of soft dorsal fin.....	<i>Lepomis cyanellus</i>
13b. (12b) Body rounded without black spot on posterior base of soft dorsal fin; lateral body with alternating stripes formed from black and red spots.....	<i>Lepomis miniatus</i>
14a. (11b) Opercle flap black to the posterior margin; opercle flap is thin near the opercle bone with the narrowest width of the flexible portion of the flap about the same diameter of the eye pupil.....	<i>Lepomis auritus</i>
14b. (11b) Opercle flap black and surrounded by white on the posterior margin; opercle flap is wide with narrowest width of the flexible flap is about two times the diameter of the eye pupil.....	15
15a. (14b) Twelve pectoral fin rays, 3 to 5 cheek scales; opercle flap often with white pigment form speckles, distinct red spots (white in preserved specimens) along lateral line.....	<i>Lepomis marginatus</i>
15b. (14b) Thirteen to 15 pectoral fin rays, 5 to 7 cheek scales; opercle flaps with red or white margin; 13 to 15 pectoral fin rays	<i>Lepomis megalotis</i>

FAMILY PERCIDAE—perches

- 1a. Snout conical, extends beyond upper lip; body with ≥ 14 black vertical bars.....2
- 1b. Snout less conical, does not extend beyond upper lip; body with < 14 black vertical bars or with a pattern other than vertical bars.....3
- 2a. (1a) Body with thick vertical bars, bars alternate in length from long to short; 9 to 10 long bars.....*Percina carbonaria*
- 2b. (1a) Body with 14 to 16 thin vertical bars of similar length*Percina macrolepida*
- 3a. (1b) Sides of body with large black blotches; midline of abdomen naked or with enlarged scales*Percina sciera*
- 3b. (1b) Sides of body without large black blotches; scales on abdomen normal4
- 4a. (3b) Lateral line arched upward *Etheostoma gracile*
- 4b. (3b) Lateral line straight.....5
- 5a. (4b) Lateral body with distinct series of M-shaped pigments; snout rounded and blunt*Etheostoma chlorosoma*
- 5b. (4b) Lateral body without distinct series of M-shaped pigments; snout not noticeably rounded and blunt6
- 6a. (5b) Lateral region with mottling bisected by a light colored lateral stripe.....
..... *Etheostoma parvipinne*
- 6b. (5b) Anterior portion of lateral region with black horizontal dashes and posterior portion of lateral region with 8 to 11 vertical bars; throat of live males orange.....
..... *Etheostoma spectabile*

FAMILY SCIAENIDAE—drums

Aplodinotus grunniens

FAMILY ELASSOMATIDAE—pygmy sunfishes

Elassoma zonatum

FAMILY CICHLIDAE—cichlids

- 1a. Anal fin spines 5 to 6*Herichthys cyanoguttatus*
1b. Anal fin spines < 5 (usually 3)..... *Oreochromis aureus*

FAMILY ACHIRIDAE—American soles

Trinectes maculatus

CANADIAN RIVER BASIN

KEY TO THE FAMILIES

1a. With adipose fin	2
1b. Without adipose fin	3
2a. (1a) Without barbels.....	Trouts – Salmonidae
2b. (1a) With barbels.....	Bullhead Catfishes – Ictaluridae
3a. (1b) One dorsal fin; pelvic fins without uniserial spines	4
3b. (1b) One or two dorsal fins; pelvic fins with uniserial spines	9
4a. (3a) Long anal fin with ≥ 17 fin rays	Shads – Clupiedae
4b. (3a) Short anal fin with ≤ 13 rays	5
5a. (4b) Caudal fin forked or emarginated; lateral line usually present.....	6
5b. (4b) Caudal fin truncated or rounded; lateral line usually absent	7
6a. (5a) Inferior, fleshy mouth modified for sucking; > 7 pharyngeal teeth in main row, usually ≥ 10 dorsal fin rays	Suckers – Catostomidae
6b. (5a) Mouth usually not fleshy or modified for sucking; < 7 pharyngeal teeth in main row, usually ≤ 10 dorsal fin rays.....	Carps and Minnows – Cyprinidae
7a. (5b) Mature males with rounded anal fin; males and females with 3rd anal fin ray branched, no gonopodium present	8
7b. (5b) Mature males with pointed anal fin forming a gonopodium; males and females with 3rd anal fin ray unbranched	Livebearers – Poeciliidae
8a. (7a) Body robust; teeth in single row are incisor-like and tricuspid (three points on a tooth).	Pupfishes – Cyprinodontidae
8b. (7a) Body elongate; conical (cone-shaped) pointed teeth in a single row or several rows.....	Killifishes – Fundulidae

9a. (3b) Pelvic fin position abdominal or sub-thoracic; dorsal fins widely separated	Silversides – Atherinopsidae
9b. (3b) Pelvic fin position thoracic; dorsal fins joined or, if separate, closely adjacent to one another	10
10a. (9b) Anal fin with 1 to 2 spines	Perches – Percidae
10b. (9b) Anal fin with 3 to 8 spines	11
11a. (10b) Posterior margin of operculum with a sharp spine; spiny and soft dorsal fin separate or only slightly connected; pseudobranchium present and exposed.....	Temperate Basses – Moronidae
11b. (10b) Posterior margin of operculum without a sharp spine; spiny and soft dorsal fins connected or with deep notch; pseudobranchium covered or absent.....	Sunfishes – Centrarchidae

KEY TO THE SPECIES

FAMILY CLUPEIDAE—herrings

- 1a. Twenty-nine to 33 anal fin rays; mouth subterminal and below level of middle of eye; black shoulder spot $\geq$ pupil of eye *Dorosoma cepedianum*
- 1b. Twenty-four to 28 anal fin rays; mouth terminal and at level of eye; black shoulder spot $<$ pupil of eye *Dorosoma petenense*

FAMILY CYPRINIDAE - minnows

- 1a. More than 15 soft rays on dorsal fin; dorsal and anal fins each with a strong serrated spine *Cyprinus carpio*
- 1b. Fewer than 10 soft rays on dorsal fin; dorsal and anal fins without spine 2
- 2a. (1b) Anal fin near caudal fin, distance from snout to origin of anal fin is > 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth with prominent parallel grooves *Ctenopharyngodon idella*
- 2b. (1b) Anal fin not noticeably near caudal fin: distance from snout to origin of anal fin is < 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth without prominent parallel grooves 3
- 3a. (2b) Intestine wound spirally around swim bladder; keratinous ridge on lower jaw *Campostoma anomalum*
- 3b. (2b) Intestine not wound spirally around swim bladder; keratinous ridge of lower jaw hardly evident 4
- 4a. (3b) Abdomen behind pelvic fins with a fleshy keel lacking scales; lateral line greatly decurved, distance between anterior lateral line scale and ventral most lateral line scale is > 3 scales in height *Notemigonus crysoleucas*
- 4b. (3b) Abdomen behind pelvic fin with scales; lateral line not greatly decurved, lateral line descends < 3 scales ventrally from highest point 5
- 5a. (4b) With maxillary barbels, might be small and not observable without opening the mouth or with magnification 6
- 5b. (4b) Without maxillary barbels 7

6a. (5a) Body with scattered black specks	<i>Macrhybopsis tetranema</i>
6b. (5a) Body silvery, without scattered black specks.....	<i>Platygobio gracilis</i>
7a. (5b) Thick lower lip at corners, mouth noticeably ventral; black spot at base of caudal fin	<i>Phenacobius mirabilis</i>
7b. (5b) Lower lip thin or not noticeably thick; with or without black spot at base of caudal fin.....	8
8a. (7b) Predorsal scales appear crowded, smaller than scales on lateral body or appear as overlapping scales; black spot in the middle, anterior portion of the dorsal fin	9
8b. (7b) Predorsal scales not crowded; without black spot in the middle, anterior portion of the dorsal fin	10
9a. (8a) Caudal spot, if distinct, continuous with mid-lateral stripe; lateral line incomplete; intestine long, more than twice the standard length.....	<i>Pimephales promelas</i>
9b. (8a) Caudal spot distinct from mid-lateral stripe; lateral line complete, intestine forming a short S-shaped loop	<i>Pimephales vigilax</i>
10a. (8b) Long intestine in a flat coil.....	<i>Hybognathus placitus</i>
10b. (8b) Short S-shaped intestine	11
11a. (10b) Moderately decurved lateral line; diamond-shaped scales; dark shoulder patch present; melanophores concentrated between rays of dorsal and anal fins	<i>Cyprinella lutrensis</i>
11b. (10b) Lateral line incomplete, complete-straight, or complete-slightly decurved; scales not noticeably diamond-shaped; without dark shoulder patch; melanophores concentrated along rays of dorsal and anal fins	12
12a. (11b) No distinct and separate black dash at base of dorsal fin; pharyngeal teeth count usually 1,4-4,1 or 2,4-4,2	13
12b. (11b) Distinct and separate black dash at base of dorsal fin; apparent when viewed from above; pharyngeal teeth count usually 0,4-4,0.....	14
13a. (12a) Dorsal fin origin opposite to pelvic fin origin	<i>Notropis blennioides</i>
13b. (12a) Dorsal fin origin posterior to pelvic fin origin	<i>Notropis atherinoides</i>

- 14a. (12b) Eye large, eye diameter is > snout length *Notropis stramineus*
 14b. (12b) Eye small, eye diameter is < snout length..... *Notropis girardi*

FAMILY CATOSTOMIDAE—suckers

Carpiodes carpio

FAMILY ICTALURIDAE—bullhead catfishes

- 1a. Head dorso-ventrally compressed; mouth terminal to superior *Pylodictis olivaris*
 1b. Head rounded; mouth subterminal.....2

 2a. (1b) Caudal fin rounded or shallowly emarginate.....3
 2b. (1b) Caudal fin deeply forked *Ictalurus punctatus*

 3a. (2a) Chin barbels completely or partially black; anal fin rays 17 to 24; anal fin broadly rounded *Ameiurus melas*
 3b. (2a) Chin barbels white or yellow; anal fin rays 24 to 27; margin of anal fin generally straight..... *Ameiurus natalis*

FAMILY SALMONIDAE—salmons

Oncorhynchus mykiss

FAMILY ATHERINOPSIDAE—New World silversides

Menidia audens

FAMILY FUNDULIDAE—topminnows

Fundulus kansae

FAMILY POECILIIDAE—livebearers

Gambusia affinis

FAMILY CYPRINODONTIDAE—pupfishes

Cyprinodon rubrofluviatilis

FAMILY MORONIDAE—temperate basses

Morone chrysops

FAMILY CENTRARCHIDAE—sunfishes

- 1a. Five to 8 anal spines *Pomoxis annularis*
- 1b. Three anal spines 2
- 2a. (1b) Body slender, body depth contained > 3 times into standard length 3
- 2b. (1b) Body deep, body depth contained < 3 times into standard length 4
- 3a. (2a) Dorsal fins narrowly joined at base forming a deep notch; upper jaw extends past posterior margin of eye in adults; mid-lateral stripe generally complete, rows of spots ventral to mid-lateral stripe faint and incomplete *Micropterus salmoides*
- 3b. (2a) Dorsal fins broadly joined at base forming a shallow notch; upper jaw does not reach past posterior portion of eye; bases of soft dorsal and anal fins scaled
..... *Micropterus dolomieu*
- 4a. (2b) Pectoral fins long and pointed, reach anterior portion of eye or beyond when bent forward 5
- 4b. (2b) Pectoral fins short and rounded, do not reach past eye when bent forward 7
- 5a. (4a) Opercle flap stiff to its margin, posterior margin either red or orange in live specimens *Lepomis microlophus*
- 5b. (4a) Opercle flap flexible, posterior margin not red or orange in live specimens 6
- 6a. (5b) Opercle flap black to the margin; black spot on posterior base of soft dorsal fin *Lepomis macrochirus*
- 6b. (5b) Opercle flap outlined with thick white band; lacking black spot on posterior base of soft dorsal fin *Lepomis humilis*
- 7a. (4b) Black opercle flap stiff near the posterior margin with bone supporting all or majority of the flap *Lepomis cyanellus*
- 7b. (4b) Black opercle flap flexible near the posterior margin without bone supporting majority of the flap *Lepomis megalotis*

FAMILY PERCIDAE—perches

Sander vitreus

COLORADO AND LAVACA RIVER BASINS

KEY TO THE FAMILIES

- 1a. Both eyes on one side of head; without right pectoral fin.. American Soles – Achiridae
- 1b. One eye on either side of head; with both pectoral fins.....2

- 2a. (1b) Caudal fin heterocercal or abbreviated heterocercal3
- 2b. (1b) Caudal fin homocercal4

- 3a. (2a) Body with ganoid scales; snout formed into a beak; without gular plate
..... Gars – Lepiososteidae
- 3b. (2a) Body covered with cycloid scales, snout not formed into a beak, with a gular
plate.....Bowfin – Amiidae

- 4a. (2b) One dorsal fin; pelvic fins without uniserial spines5
- 4b. (2b) One or two dorsal fins; pelvic fins with uniserial spines13

- 5a. (4a) With adipose fin.....6
- 5b. (4a) Without adipose fin8

- 6a. (5a) Without barbels.....7
- 6b. (5a) With barbels..... Bullhead Catfishes – Ictaluridae

- 7a. (6a) Scales large, < 50 lateral line scales; incisor teeth presentTetras – Characidae
- 7b. (6a) Scales small, > 60 lateral line scales; incisor teeth absent Trouts – Salmonidae

- 8a. (5b) Long anal fin with ≥ 17 fin rays Shads – Clupiedae
- 8b. (5b) Short anal fin with ≤ 13 rays9

- 9a. (8b) Caudal fin forked or emarginated; lateral line usually present.....10
- 9b. (8b) Caudal fin truncated or rounded; lateral line usually absent11

10a. (9a) Inferior, fleshy mouth modified for sucking; > 7 pharyngeal teeth in main row, usually ≥ 10 dorsal fin rays	Suckers – Catostomidae
10b. (9a) Mouth usually not fleshy or modified for sucking; < 7 pharyngeal teeth in main row, usually ≤ 10 dorsal fin rays.....	Carps and Minnows – Cyprinidae
11a. (9b) Mature males with rounded anal fin; males and females with 3rd anal fin ray branched, no gonopodium present	12
11b. (9b) Mature males with pointed anal fin forming a gonopodium; males and females with 3rd anal fin ray unbranched	Livebearers – Poeciliidae
12a. (11a) Body robust; teeth in single row are incisor-like and tricuspid (three points on a tooth).	Pupfishes – Cyprinodontidae
12b. (11a) Body elongate; conical (cone-shaped) pointed teeth in a single row or several rows.....	Killifishes – Fundulidae
13a. (4b) Anus anterior to pelvic fins; > 5 soft rays on each pelvic fin.....	Pirate perch – Aphredoderidae
13b. (4b) Anus posterior to pelvic fins; 5 soft rays on pelvic fins.....	14
14a. (13b) Pelvic fin position abdominal or sub-thoracic; dorsal fins widely separated...	15
14b. (13b) Pelvic fin position thoracic; dorsal fins joined or, if separate, closely adjacent to one another.....	16
15a. (14a) Dorsal fin with 4 thick spines; anal fin with 2-3 spines; adipose eyelids present	Mullets – Mugilidae
15b. (14a) Dorsal fin with 4 to 8 thin spines; anal fin with 1 spine; adipose eyelids absent	Silversides – Atherinopsidae
16a. (14b) One nostril (nare) on each side of head; lateral line interrupted	Cichlids – Cichlidae
16b. (14b) Two nostrils (nares) on each side of head; lateral line complete, incomplete, or absent	17

17a. (16b) Dorsal fin with > 23 fin rays; lateral line extends to tip of caudal fin.....	
.....	Drums – Sciaenidae
17b. (16b) Dorsal fin with < 23 fin rays; lateral line, if present, does not extend to tip of caudal fin.....	18
18a. (17b) Pelvic fins joined into a sucking disk, gill membranes broadly joined to isthmus	Gobies – Gobiidae
18b. (17b) Pelvic fins not joined, gill membranes free or nearly free from isthmus (may be joined to each other across isthmus)	19
19a. (18b) Anal fin with 1 to 2 spines.....	Perches – Percidae
19b. (18b) Anal fin with 3 to 8 spines	20
20a. (19b) Posterior margin of operculum with a sharp spine; spiny and soft dorsal fin separate or only slightly connected; pseudobranchium present and exposed.....	
.....	Temperate Basses – Moronidae
20b. (19b) Posterior margin of operculum without a sharp spine; spiny and soft dorsal fins connected or with deep notch; pseudobranchium covered or absent.....	
.....	Sunfishes – Centrarchidae

KEY TO THE SPECIES

FAMILY LEPISOSTEIDAE—gars

- 1a. Large teeth in upper jaw in parallel rows on each side *Atractosteus spatula*
1b. Large teeth in upper jaw one row, although another non-parallel row might be present 2
- 2a. (1b) Beak long and narrow, least width goes about 12 to 20 times in length; width of beak at nostrils < eye diameter; snout > $\frac{2}{3}$ of head length *Lepisosteus osseus*
2b. (1b) Beak short and blunt, least width goes about 5 to 7 times in length; width of beak at nostrils > eye diameter; snout < $\frac{2}{3}$ of head length *Lepisosteus oculatus*

FAMILY AMIIDAE—bowfins

Amia calva

FAMILY ANGUILLIDAE—freshwater eels

Anguilla rostrata

FAMILY CLUPEIDAE—herrings

- 1a. Twenty-nine to 33 anal fin rays; mouth subterminal and below level of middle of eye; black shoulder spot $\geq$ pupil of eye *Dorosoma cepedianum*
1b. Twenty-four to 28 anal fin rays; mouth terminal and at level of eye; black shoulder spot < pupil of eye *Dorosoma petenense*

FAMILY CYPRINIDAE - minnows

- 1a. More than 15 soft rays on dorsal fin; dorsal and anal fins each with a strong serrated spine 2
1b. Fewer than 10 soft rays on dorsal fin; dorsal and anal fins without spine 3
- 2a. (1a) Upper jaw with two pairs of barbels *Cyprinus carpio*
2b. (1a) Upper jaw without barbels *Carassius auratus*

3a. (2b) Anal fin near caudal fin, distance from snout to origin of anal fin is > 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth with prominent parallel grooves	<i>Ctenopharyngodon idella</i>
3b. (2b) Anal fin not noticeably near caudal fin: distance from snout to origin of anal fin is < 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth without prominent parallel grooves	4
4a. (3b) Intestine wound spirally around swim bladder; keratinous ridge on lower jaw	<i>Campostoma anomalum</i>
4b. (3b) Intestine not wound spirally around swim bladder; keratinous ridge of lower jaw hardly evident.....	5
5a. (4b) Abdomen behind pelvic fins with a fleshy keel lacking scales; lateral line greatly decurved, distance between anterior lateral line scale and ventral most lateral line scale is > 3 scales in height.....	<i>Notemigonus crysoleucas</i>
5b. (4b) Abdomen behind pelvic fin with scales; lateral line not greatly decurved, lateral line descends < 3 scales ventrally from highest point	6
6a. (5b) With maxillary barbels, might be small and not observable without opening the mouth or with magnification.....	7
6b. (5b) Without maxillary barbels	8
7a. (6a) Prominent mid-lateral stripe reaching from opercle to caudal peduncle	<i>Macrhybopsis marconis</i>
7b. (6a) Mid-lateral stripe incomplete or absent, more pronounced posteriorly on caudal peduncle when incomplete.....	<i>Macrhybopsis hyostoma</i>
8a. (6b) Thick lower lip at corners, mouth noticeably ventral; black spot at base of caudal fin	<i>Phenacobius mirabilis</i>
8b. (6b) Lower lip thin or not noticeably thick; with or without black spot at base of caudal fin.....	9
9a. (8b) Predorsal scales appear crowded, smaller than scales on lateral body or appear as overlapping scales; black spot in the middle, anterior portion of the dorsal fin	10
9b. (8b) Predorsal scales not crowded; without black spot in the middle, anterior portion of the dorsal fin	11

10a. (9a) Caudal spot, if distinct, continuous with mid-lateral stripe; lateral line incomplete; intestine long, more than twice the standard length.....	<i>Pimephales promelas</i>
10b. (9a) Caudal spot distinct from mid-lateral stripe; lateral line complete, intestine forming a short S-shaped loop	<i>Pimephales vigilax</i>
11a. (9b) Long intestine in a flat coil.....	12
11b. (9b) Short S-shaped intestine	13
12a. (11a) Black mid-lateral stripe extends through eye to snout; eye width greater than or equal to snout length.....	<i>Dionda nigrotaeniata</i>
12b. (11a) Mid-lateral stripe, if present (sometimes appears as a broad, diffuse band of melanophores), does not extend through the eye to the snout; eye width less than snout length.....	<i>Hybognathus placitus</i>
13a. (11b) Moderately decurved lateral line; diamond-shaped scales; dark shoulder patch present; melanophores concentrated between rays of dorsal and anal fins	14
13b. (11b) Lateral line incomplete, complete-straight, or complete-slightly decurved; scales not noticeably diamond-shaped; without dark shoulder patch; melanophores concentrated along rays of dorsal and anal fins	15
14a. (13a) Sub-terminal mouth; caudal fin base with a spot larger than eye	<i>Cyprinella venusta</i>
14b. (13a) Terminal mouth; no caudal spot	<i>Cyprinella lutrensis</i>
15a. (13b) Distinct and separate black dash at base of dorsal fin; apparent when viewed from above; pharyngeal teeth count usually 0,4-4,0.....	16
15b. (13b) No distinct and separate black dash at base of dorsal fin; pharyngeal teeth count usually 1,4-4,1 or 2,4-4,2	19
16a. (15a) Lateral line scales markedly elevated (taller than wide) anteriorly, elevated scale height 2 to 5 times scale width.....	17
16b. (15a) Lateral line scales not markedly elevated anteriorly, scale height 1 to 2 times scale width	18

17a. (16a) Dorsal and lateral body with melanophores outlining scales; with pronounced black lateral stripe; dorsal fin height goes 2.1 or more times in pre-dorsal length; infraorbital canal complete	<i>Notropis volucellus</i>
17b. (16a) Dorsal and lateral body with sparse melanophores; scales outlined with melanophores are rare; pre-dorsal black spot is prominent and distinct from mid-dorsal stripe; dorsal fin height goes 2.0 or fewer times in pre-dorsal length; infraorbital canal incomplete.....	<i>Notropis buchanani</i>
18a. (16b) Eye large, eye diameter is > snout length.....	<i>Notropis stramineus</i>
18b. (16b) Eye small, eye diameter is < snout length.....	<i>Notropis buccula</i>
19a. (15b) Depressed dorsal fin longer than head.....	<i>Hybopsis amnis</i>
19b. (15b) Depressed dorsal fin shorter than head	20
20a. (19b) Dorsal fin origin opposite or anterior to pelvic fin origin	21
20b. (19b) Dorsal fin origin posterior to pelvic fin origin	24
21a. (20a) Prominent mid-lateral stripe; extending through eye	22
21b. (20a) No prominent mid-lateral stripe present.....	<i>Notropis shumardi</i>
22a. (21a) Pharyngeal teeth 5-5; mouth small and almost vertical.....	<i>Opsopoeodus emiliae</i>
22b. (21a) Pharyngeal teeth are 1,4-4,1 or 2,4-4,2; mouth large and oblique	<i>Notropis texanus</i>
23a. (20b) Small scales, ≥ 41 lateral line scales, > 25 predorsal scales....	<i>Lythrurus fumeus</i>
23b. (20b) Moderate-sized scales, ≤ 40 lateral line scales, < 24 predorsal scales	24
24a. (23b) Eye larger, eye diameter > snout length	<i>Notropis amabilis</i>
24b. (23b) Eye smaller, eye diameter < snout length	<i>Notropis oxyrhynchus</i>

FAMILY CATOSTOMIDAE—suckers

1a. Dorsal fin long, base > than $\frac{1}{3}$ of standard length; 22 to 30 dorsal fin rays	2
1b. Dorsal fin short, base < than $\frac{1}{4}$ of standard length; 4 to 18 dorsal fin rays	5

- 2a. (1a) Small scales, lateral line scales > 50; eye closer to back of head than to tip of snout; head abruptly more slender than body; papillose lips..... *Cycleptus elongatus*
- 2b. (1a) Large scales, lateral line scales < 45; eye closer to tip of snout than back of head; plicate lips3
- 3a. (2b) Subopercle triangular, broadest toward base; knob present at tip of lower lip; blunt snout, forming level with eye *Carpiodes carpio*
- 3b. (2b) Subopercle semicircular, broadest towards middle; knob absent at tip of lower lip; rounded snout, forming below level of eye4
- 4a. (3b) Body elongate and slender, greatest body depth goes 2.6 to 3.3 times in standard length, and height of anterior rays in dorsal and anal fins often less than 2/3 head length in individuals >300 mm; small eye, eye diameter goes ≥ 2 times in snout length of individuals <300 mm *Ictiobus niger*
- 4b. (3b) Body deep and narrow, greatest body depth goes 2.2 to 2.8 times in standard length, and height of anterior dorsal and anal fin rays often greater than 2/3 head length in individuals >300 mm; large eye, eye diameter goes ≤ 2 times in snout length of individuals <300 mm *Ictiobus bubalus*
- 5a. (1b) Lateral line complete and well developed; air bladder with 3 chambers; no rows of spots present *Moxostoma congestum*
- 5b. (1b) Lateral line incomplete or absent; air bladder with 2 chambers; rows of spots present *Minytrema melanops*

FAMILY CHARACIDAE—characins

Astyanax mexicanus

FAMILY ICTALURIDAE—bullhead catfishes

- 1a. Adipose fin joined to the caudal fin or separated by a shallow notch.... *Noturus gyrinus*
- 1b. Adipose fin free at tip, not joined to caudal fin2
- 2a. (1b) Head dorso-ventrally compressed; mouth terminal to superior . *Pylodictis olivaris*
- 2b. (1b) Head rounded; mouth subterminal3
- 3a. (2b) Caudal fin rounded or shallowly emarginate.....4
- 3b. (2b) Caudal fin deeply forked5

- 4a. (3a) Chin barbels completely or partially black; anal fin rays 17 to 24; anal fin broadly rounded*Ameiurus melas*
- 4b. (3a) Chin barbels white or yellow; anal fin rays 24 to 27; margin of anal fin generally straight.....*Ameiurus natalis*
- 5a. (3b) Anal fin rays 30 to 36; anal fin free margin is straight; medial keel-like ridge anterior to dorsal fin forms humped back appearance*Ictalurus furcatus*
- 5b. (3b) Anal fin rays 22 to 29; anal fin free margin is rounded; no humped back appearance.....6
- 6a. (5b) Anal fin rays 27 to 29; pectoral fin spine goes < 5 times into standard length; random scattering of few black spots may be present*Ictalurus punctatus*
- 6b. (5b) Anal fin rays 22 to 26; pectoral fin spine goes > 5 times into standard length; diffuse black spots on sides..... *Ictalurus lupus*

FAMILY SALMONIDAE—salmons

Oncorhynchus mykiss

FAMILY APHREDODERIDAE—pirate perch

Aphredoderus sayanus

FAMILY MUGILIDAE—mulletts

- 1a. Lower jaw rounded, without a symphyseal knob; lower limb of 1st gill arch with 17 to 20 gill rakers; no adipose eyelid; scales ctenoid*Agonostomus monticola*
- 1b. Lower jaw angular, with a prominent symphyseal knob; lower limb of 1st gill arch with 25 to 60 gill rakers; adipose eyelid well developed in adults; scales cycloid in young, ctenoid in adults.*Mugil cephalus*

FAMILY ATHERINOPSIDAE—New World silversides

Menidia audens

FAMILY FUNDULIDAE—topminnows

- 1a. Distance from origin of dorsal fin to end of hypural plate < distance from origin of dorsal fin to preopercle or occasionally about equal to that distance; more than 30 longitudinal scale rows2
- 1b. Distance from origin of dorsal fin to end of hypural plate > distance from origin of dorsal fin to preopercle; 30 or fewer longitudinal scale rows..... *Lucania parva*
- 2a. (1a) More than 40 longitudinal scale rows; dark vertical barring; gill slit not extending dorsal to uppermost pectoral fin ray*Fundulus zebrinus*
- 2b. (1a) Fewer than 40 longitudinal scale rows; gill slit extending dorsal to uppermost pectoral fin ray3
- 3a. (2b) Body with a distinct black lateral band*Fundulus notatus*
- 3b. (2b) Body without a distinct black lateral band4
- 4a. (3b) Dorsal fin originating posterior to anal fin origin *Fundulus chrysotus*
- 4b. (3b) Dorsal fin originating anterior to anal fin origin; > 15 scale rows from pelvic fin origin to isthmus; predorsal stripe absent or not reaching occiput *Fundulus grandis*

FAMILY CYPRINODONTIDAE—pupfishes

- 1a. Abdomen with scales anterior to pelvic fins; distance from origin of dorsal fin to end of hypural plate > distance from origin of dorsal to anterior nostril. *Cyprinodon variegatus*
- 1b. Abdomen without scales anterior to pelvic fins; distance from origin of dorsal fin to end of hypural plate < the distance from origin of dorsal to anterior nostril *Cyprinodon rubrofluviatilis*

FAMILY POECILIIDAE—livebearers

- 1a. Origin of dorsal fin anterior to anal fin origin; intestinal canal long with many convolutions2
- 1b. Origin of dorsal fin posterior to anal fin origin; intestinal canal short with few convolutions3
- 2a. (1a) Teeth in single row; dorsal fin rays ≥ 12 ; parallel rows of spots usually present*Poecilia latipinna*
- 2b. (1a) Teeth in villiform bands; dorsal fin rays ≤ 12 ; spots, if present, are diffuse*Xiphophorus variatus*

- 3a. (1b) Spines at tip of 3rd anal fin ray of male gonopodium (first enlarged ray) 1 to 3 times longer than wide *Gambusia affinis*
- 3b. (1b) Spines at tip of 3rd anal fin ray of male gonopodium 4 to 10 times longer than wide4
- 4a. (3b) Dorsal and anal fins without yellow pigmentation; dusky lateral stripe indistinct; mouth without black markings and anal spot of females not restricted to area immediately around anus; pectoral fin of males with indentation, much deeper than widest pectoral fin ray; found in Clear Creek, Menard County only *Gambusia heterochir*
- 4b. (3b) Dorsal and (in females) anal fins with yellow pigmentation (lost in preservation); males with a shallow pectoral indentation *Gambusia geiseri*

FAMILY MORONIDAE—temperate basses

- 1a. Body depth goes < 3 times in standard length; teeth in single patch on back of tongue.....*Morone chrysops*
- 1b. Body depth goes > 3 times in standard length; teeth in 2 parallel patches on back of tongue.....*Morone saxatilis*

FAMILY CENTRARCHIDAE—sunfishes

- 1a. Five to 8 anal spines2
- 1b. Three anal spines.....3
- 2a. (1a) Dorsal fin set back on body, length of dorsal fin base < distance from its origin to posterior margin of eye; lateral body with wide to narrow dorsal black bands; ≤ 6 dorsal spines..... *Pomoxis annularis*
- 2b. (1a) Dorsal fin set forward on body, length of dorsal fin base equal to or greater than distance from its origin to posterior margin of eye; lateral body with checkerboard black and light pattern; ≥7 dorsal spines*Pomoxis nigromaculatus*
- 3a. (1b) Body slender, body depth contained > 3 times into standard length.....4
- 3b. (1b) Body deep, body depth contained < 3 times into standard length.....7
- 4a. (3a) Dorsal fins narrowly joined at base forming a deep notch; upper jaw extends past posterior margin of eye in adults; mid-lateral stripe generally complete, rows of spots ventral to mid-lateral stripe faint and incomplete*Micropterus salmoides*
- 4b. (3a) Dorsal fins broadly joined at base forming a shallow notch; upper jaw does not reach past posterior portion of eye; bases of soft dorsal and anal fins scaled5

5a. (4b) No tooth patch on tongue; lower lateral region scales without black spots forming horizontal rows.....	<i>Micropterus dolomieu</i>
5b. (4b) Tooth patch on tongue; lower lateral region scales with black spots forming horizontal rows.....	6
6a. (5b) Mid-lateral stripe often appears interrupted anteriorly, rows of spots ventral to mid-lateral stripe distinct and complete.	<i>Micropterus punctulatus</i>
6b. (5b) Dark wide midlateral stripe present and disconnected anteriorly into a narrow midlateral stripe posteriorly, forming vertical bars.....	<i>Micropterus treculii</i>
7a. (3b) Teeth on tongue; head and opercle with 3 to 5 distinct dark and light longitudinal stripes; red spot on posterior margin of opercle flap in fresh specimens....	<i>Lepomis gulosus</i>
7b. (3b) No teeth on tongue; head and opercle lacking distinct dark and light longitudinal stripes	8
8a. (7b) Pectoral fins long and pointed, reach anterior portion of eye or beyond when bent forward.....	9
8b. (7b) Pectoral fins short and rounded, do not reach past eye when bent forward	11
9a. (8a) Opercle flap stiff to its margin, posterior margin either red or orange in live specimens	<i>Lepomis microlophus</i>
9b. (8a) Opercle flap flexible, posterior margin not red or orange in live specimens	10
10a. (9b) Opercle flap black to the margin; black spot on posterior base of soft dorsal fin	<i>Lepomis macrochirus</i>
10b. (9b) Opercle flap outlined with thick white band; lacking black spot on posterior base of soft dorsal fin.....	<i>Lepomis humilis</i>
11a. (8b) Black opercle flap stiff near the posterior margin with bone supporting all or majority of the flap.....	12
11b. (8b) Black opercle flap flexible near the posterior margin without bone supporting majority of the flap.....	14
12a. (11a) Lateral line incomplete; smaller individuals with black spot surrounded by white margin on posterior base of soft dorsal fin	<i>Lepomis symmetricus</i>
12b. (11a) Lateral line complete; black spot, if present, on posterior base of soft dorsal fin without white margin	13

- 13a. (12b) Body elongated with black spot on posterior base of soft dorsal fin.....*Lepomis cyanellus*
- 13b. (12b) Body rounded without black spot on posterior base of soft dorsal fin; lateral body with alternating stripes formed from black and red spots.....*Lepomis miniatus*
- 14a. (11b) Opercle flap black to the posterior margin; opercle flap is thin near the opercle bone with the narrowest width of the flexible portion of the flap about the same diameter of the eye pupil.....*Lepomis auritus*
- 14b. (11b) Opercle flap black and surrounded by white on the posterior margin; opercle flap is wide with narrowest width of the flexible flap is about two times the diameter of the eye pupil..... *Lepomis megalotis*

FAMILY PERCIDAE—perches

- 1a. Snout conical, extends beyond upper lip; body with ≥ 14 black vertical bars.....2
- 1b. Snout less conical, does not extend beyond upper lip; body with < 14 black vertical bars or with a pattern other than vertical bars.....3
- 2a. (1a) Body with thick vertical bars, bars alternate in length from long to short; 9 to 10 long bars.....*Percina carbonaria*
- 2b. (1a) Body with 14 to 16 thin vertical bars of similar length.....*Percina macrolepidota*
- 3a. (1b) Sides of body with large black blotches; midline of abdomen naked or with enlarged scales*Percina sciera*
- 3b. (1b) Sides of body without large black blotches; scales on abdomen normal4
- 4a. (3b) Lateral line short, < 6 pored scales; single row of horizontal dashes present*Etheostoma proeliare*
- 4b. (3b) Lateral line long (complete or incomplete), > 6 pored scales; if horizontal dashes present, accompanied by vertical bars5
- 5a. (4b) Lateral line arched upward *Etheostoma gracile*
- 5b. (4b) Lateral line straight.....6

- 6a. (5b) Lateral body with distinct series of M-shaped pigments; snout rounded and blunt*Etheostoma chlorosoma*
- 6b. (5b) Lateral body without distinct series of M-shaped pigments; snout not noticeably rounded and blunt7
- 7a. (6b) Lateral region with mottling bisected by a light colored lateral stripe.....
.....*Etheostoma parvipinne*
- 7b. (6b) Lateral region without mottling bisected by a light colored lateral stripe8
- 8a. (7b) Anterior portion of lateral region with black horizontal dashes and posterior portion of lateral region with vertical bars; uninterrupted supratemporal canal; throat of live males orange; no reddish orange spots on sides *Etheostoma spectabile*
- 8b. (7b) Lateral region with vertical bars, horizontal dashes on anterior portion sometimes visible, but obscured by vertical bars; interrupted supratemporal canal; throat of live males blue or green; sides of live males scattered with reddish orange spots
.....*Etheostoma lepidum*

FAMILY SCIAENIDAE—drums

Aplodinotus grunniens

FAMILY CICHLIDAE—cichlids

- 1a. Anal fin spines 5 to 6*Herichthys cyanoguttatus*
- 1b. Anal fin spines < 5 (usually 3).....*Oreochromis aureus*

FAMILY GOBIIDAE—gobies

Gobiosoma bosc

FAMILY ACHIRIDAE—American soles

Trinectes maculatus

GUADALUPE AND SAN ANTONIO RIVER BASINS

KEY TO THE FAMILIES

- 1a. Both eyes on one side of head; without right pectoral fin.. American Soles – Achiridae
- 1b. One eye on either side of head; with both pectoral fins.....2

- 2a. (1a) Body without pelvic fins.....3
- 2b. (1a) Body with pelvic fins.....4

- 3a. (2a) Dorsal fin attached to caudal fin Freshwater Eels – Anguillidae
- 3b. (2a) Dorsal fin not attached to caudal fin..... Pipefishes – Syngnathidae

- 4a. (2b) Caudal fin heterocercal or abbreviated heterocercal Gars – Lepiososteidae
- 4b. (2b) Caudal fin homocercal5

- 5a. (4b) One dorsal fin; pelvic fins without uniserial spines6
- 5b. (4b) One or two dorsal fins; pelvic fins with uniserial spines15

- 6a. (5a) With adipose fin.....7
- 6b. (5a) Without adipose fin10

- 7a. (4a) Without barbels.....8
- 7b. (4a) With barbels.....9

- 8a. (6a) Scales large, < 50 lateral line scales; incisor teeth presentTetras – Characidae
- 8b. (6a) Scales small, > 60 lateral line scales; incisor teeth absent Trouts – Salmonidae

- 9a. (7b) Body covered with bony plates; head with one pair of barbels.....
.....Armored Catfishes – Loricariidae
- 9b. (7b) Scales absent; head with four to eight barbels Bullhead Catfishes – Ictaluridae

10a. (6b) Long anal fin with ≥ 17 fin rays	Shads – Clupiedae
10b. (6b) Short anal fin with ≤ 13 rays	11
11a. (10b) Caudal fin forked or emarginated; lateral line usually present.....	12
11b. (10b) Caudal fin truncated or rounded; lateral line usually absent	13
12a. (11a) Inferior, fleshy mouth modified for sucking; > 7 pharyngeal teeth in main row, usually ≥ 10 dorsal fin rays	Suckers – Catostomidae
12b. (11a) Mouth usually not fleshy or modified for sucking; < 7 pharyngeal teeth in main row, usually ≤ 10 dorsal fin rays.....	Carps and Minnows – Cyprinidae
13a. (11b) Mature males with rounded anal fin; males and females with 3rd anal fin ray branched, no gonopodium present	14
13b. (11b) Mature males with pointed anal fin forming a gonopodium; males and females with 3rd anal fin ray unbranched	Livebearers – Poeciliidae
14a. (13a) Body robust; teeth in single row are incisor-like and tricuspid (three points on a tooth)	Pupfishes – Cyprinodontidae
14b. (13a) Body elongate; conical (cone-shaped) pointed teeth in a single row or several rows.....	Killifishes – Fundulidae
15a. (5b) Pelvic fin position abdominal or sub-thoracic; dorsal fins widely separated.....	16
15b. (5b) Pelvic fin position thoracic; dorsal fins joined or, if separate, closely adjacent to one another.....	17
16a. (15a) Dorsal fin with 4 thick spines; anal fin with 2-3 spines; adipose eyelids present	Mullets – Mugilidae
16b. (15a) Dorsal fin with 4 to 8 thin spines; anal fin with 1 spine; adipose eyelids absent	Silversides – Atherinopsidae
17a. (15b) One nostril (nare) on each side of head; lateral line interrupted	Cichlids – Cichlidae
17b. (15b) Two nostrils (nares) on each side of head; lateral line complete, incomplete, or absent	18

18a. (17b) Dorsal fin with > 23 fin rays; lateral line extends to tip of caudal fin.....	
.....	Drums – Sciaenidae
18b. (17b) Dorsal fin with < 23 fin rays; lateral line, if present, does not extend to tip of caudal fin.....	19
19a. (17b) Anal fin with 1 to 2 spines.....	Perches – Percidae
19b. (17b) Anal fin with 3 to 8 spines	20
20a. (19b) Posterior margin of operculum with a sharp spine; spiny and soft dorsal fin separate or only slightly connected; pseudobranchium present and exposed.....	
.....	Temperate Basses – Moronidae
20b. (19b) Posterior margin of operculum without a sharp spine; spiny and soft dorsal fins connected or with deep notch; pseudobranchium covered or absent.....	
.....	Sunfishes – Centrarchidae

KEY TO THE SPECIES

FAMILY LEPISOSTEIDAE—gars

- 1a. Large teeth in upper jaw in parallel rows on each side *Atractosteus spatula*
- 1b. Large teeth in upper jaw one row, although another non-parallel row might be present 2
- 2a. (1b) Beak long and narrow, least width goes about 12 to 20 times in length; width of beak at nostrils < eye diameter; snout > $\frac{2}{3}$ of head length *Lepisosteus osseus*
- 2b. (1b) Beak short and blunt, least width goes about 5 to 7 times in length; width of beak at nostrils > eye diameter; snout < $\frac{2}{3}$ of head length *Lepisosteus oculatus*

FAMILY ANGUILLIDAE—freshwater eels

Anguilla rostrata

FAMILY CLUPEIDAE—herrings

- 1a. Twenty-nine to 33 anal fin rays; mouth subterminal and below level of middle of eye; black shoulder spot $\geq$ pupil of eye *Dorosoma cepedianum*
- 1b. Twenty-four to 28 anal fin rays; mouth terminal and at level of eye; black shoulder spot < pupil of eye *Dorosoma petenense*

FAMILY CYPRINIDAE - minnows

- 1a. More than 15 soft rays on dorsal fin; dorsal and anal fins each with a strong serrated spine 2
- 1b. Fewer than 10 soft rays on dorsal fin; dorsal and anal fins without spine 3
- 2a. (1a) Upper jaw with two pairs of barbels *Cyprinus carpio*
- 2b. (1a) Upper jaw without barbels *Carassius auratus*
- 3a. (1b) Anal fin near caudal fin, distance from snout to origin of anal fin is > 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth with prominent parallel grooves *Ctenopharyngodon idella*
- 3b. (1b) Anal fin not noticeably near caudal fin: distance from snout to origin of anal fin is < 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth without prominent parallel grooves 4

4a. (3b) Intestine wound spirally around swim bladder; keratinous ridge on lower jaw	<i>Campostoma anomalum</i>
4b. (3b) Intestine not wound spirally around swim bladder; keratinous ridge of lower jaw hardly evident.....	5
5a. (4b) Abdomen behind pelvic fins with a fleshy keel lacking scales; lateral line greatly decurved, distance between anterior lateral line scale and ventral most lateral line scale is > 3 scales in height.....	<i>Notemigonus crysoleucas</i>
5b. (4b) Abdomen behind pelvic fin with scales; lateral line not greatly decurved, lateral line descends < 3 scales ventrally from highest point	6
6a. (5b) With maxillary barbels, might be small and not observable without opening the mouth or with magnification.....	<i>Macrhybopsis marconis</i>
6b. (5b) Without maxillary barbels	7
7a. (6b) Predorsal scales appear crowded, smaller than scales on lateral body or appear as overlapping scales; black spot in the middle, anterior portion of the dorsal fin	8
7b. (6b) Predorsal scales not crowded; without black spot in the middle, anterior portion of the dorsal fin	9
8a. (7a) Caudal spot, if distinct, continuous with mid-lateral stripe; lateral line incomplete; intestine long, more than twice the standard length.....	<i>Pimephales promelas</i>
8b. (7a) Caudal spot distinct from mid-lateral stripe; lateral line complete, intestine forming a short S-shaped loop	<i>Pimephales vigilax</i>
9a. (7b) Long intestine in a flat coil; black mid-lateral stripe extends through eye to snout.....	<i>Dionda nigrotaeniata</i>
9b. (7b) Short S-shaped intestine	10
10a. (9b) Moderately decurved lateral line; diamond-shaped scales; dark shoulder patch present; melanophores concentrated between rays of dorsal and anal fins	11
10b. (9b) Lateral line incomplete, complete-straight, or complete-slightly decurved; scales not noticeably diamond-shaped; without dark shoulder patch; melanophores concentrated along rays of dorsal and anal fins	13
11a. (10a) Terminal mouth	<i>Cyprinella lutrensis</i>

11b. (10a) Sub-terminal mouth	12
12a. (11b) Caudal fin base with a large black spot, about size of eye <i>Cyprinella venusta</i>	
12b. (11b) Caudal fin base without a large black spot..... <i>Cyprinella lepida</i>	
13a. (10b) Distinct and separate black dash at base of dorsal fin; apparent when viewed from above; pharyngeal teeth count usually 0,4-4,0	14
13b. (10b) No distinct and separate black dash at base of dorsal fin; pharyngeal teeth count usually 1,4-4,1 or 2,4-4,2	16
14a. (13a) Lateral line scales markedly elevated (taller than wide) anteriorly, elevated scale height 2 to 5 times scale width.....	15
14b. (13a) Lateral line scales not markedly elevated anteriorly, scale height 1 to 2 times scale width	<i>Notropis stramineus</i>
15a. (14a) Dorsal and lateral body with melanophores outlining scales; with pronounced black lateral stripe; dorsal fin height goes 2.1 or more times in pre-dorsal length; infraorbital canal complete	<i>Notropis volucellus</i>
15b. (14a) Dorsal and lateral body with sparse melanophores; scales outlined with melanophores are rare; pre-dorsal black spot is prominent and distinct from mid-dorsal stripe; dorsal fin height goes 2.0 or fewer times in pre-dorsal length; infraorbital canal incomplete.....	<i>Notropis buchanani</i>
16a. (13b) Depressed dorsal fin longer than head.....	<i>Hybopsis amnis</i>
16b. (13b) Depressed dorsal fin shorter than head	17
17a. (16a) Dorsal fin origin opposite or anterior to pelvic fin origin	18
17b. (16a) Dorsal fin origin posterior to pelvic fin origin	20
18a. (17a) Pharyngeal teeth 5-5; mouth small and almost vertical..... <i>Opsopoeodus emiliae</i>	
18b. (17a) Pharyngeal teeth are 1,4-4,1 or 2,4-4,2; mouth large and oblique	19
19a. (18b) Usually 8 anal fin rays; inside of mouth with black melanophores; dorsal fin insertion is opposite to pelvic fin insertion	<i>Notropis chalybaeus</i>
19b. (18b) Usually 7 anal fin rays; inside of mouth without black melanophores; dorsal fin insertion is anterior to pelvic fin insertion.....	<i>Notropis texanus</i>

- 20a. (17b) 32 – 36 lateral line scales; melanophores concentrated on upper and lower jaws; predorsal scales are not crowded *Notropis amabilis*
- 20b. (17b) 41 – 45 lateral line scales; melanophores scattered on chin; crowded predorsal scales *Lythrurus fumeus*

FAMILY CATOSTOMIDAE—suckers

- 1a. Dorsal fin long, base > than $\frac{1}{3}$ of standard length; 22 to 30 dorsal fin rays2
- 1b. Dorsal fin short, base < than $\frac{1}{4}$ of standard length; 4 to 18 dorsal fin rays4
- 2a. (1a) Small scales, lateral line scales > 50; eye closer to back of head than to tip of snout; head abruptly more slender than body; papillose lips *Cycleptus elongatus*
- 2b. (1a) Large scales, lateral line scales < 45; eye closer to tip of snout than back of head; plicate lips3
- 3a. (2b) Subopercle triangular, broadest toward base; knob present at tip of lower lip; blunt snout, forming level with eye *Carpionodes carpio*
- 3b. (2b) Subopercle semicircular, broadest towards middle; knob absent at tip of lower lip rounded snout, forming below level of eye *Ictiobus bubalus*
- 4a. (1b) Lateral line complete and well developed; air bladder with 3 chambers *Moxostoma congestum*
- 4b. (1b) Lateral line absent in adults; air bladder with 2 chambers; color pattern (except in young with 2 dark stripes) consists of narrow vertical bars; back with crescentic scale marks *Erimyzon sucetta*

FAMILY CHARACIDAE—characins

Astyanax mexicanus

FAMILY ICTALURIDAE—bullhead catfishes

- 1a. Eyes absent; skin without pigment2
- 1b. Eyes present; skin pigmented3
- 2a. (1a) No teeth on jaws; lips at corner of mouth thin *Trogloglanis pattersoni*
- 2b. (1a) Well developed teeth on jaws; lips at corner of mouth thick *Satan eurystomus*

3a. (1b) Adipose fin joined to the caudal fin or separated by a shallow notch	4
3b. (1b) Adipose fin free at tip, not joined to caudal fin.....	5
4a. (3a) Mouth terminal; pectoral fin spine not serrated; lower lip and chin not heavily speckled with black pigment.....	<i>Noturus gyrinus</i>
4b. (3a) Mouth sub-terminal; pectoral fin spine serrated; lower lip and chin heavily speckled with black pigment.....	<i>Noturus nocturnus</i>
5a. (3b) Head dorso-ventrally compressed; mouth terminal to superior .	<i>Pylodictis olivaris</i>
5b. (3b) Head rounded; mouth subterminal	6
6a. (5b) Caudal fin rounded or shallowly emarginate.....	7
6b. (5b) Caudal fin deeply forked	8
7a. (6a) Chin barbels completely or partially black; anal fin rays 17 to 24; anal fin broadly rounded	<i>Ameiurus melas</i>
7b. (6a) Chin barbels white or yellow; anal fin rays 24 to 27; margin of anal fin generally straight.....	<i>Ameiurus natalis</i>
8a. (6b) Anal fin rays 30 to 36; anal fin free margin is straight; medial keel-like ridge anterior to dorsal fin forms humped back appearance	<i>Ictalurus furcatus</i>
8b. (6b) Anal fin rays 22 to 29; anal fin free margin is rounded; no humped back appearance.....	9
9a. (8b) Anal fin rays 27 to 29; pectoral fin spine goes < 5 times into standard length; random scattering of few black spots may be present	<i>Ictalurus punctatus</i>
9b. (8b) Anal fin rays 22 to 26; pectoral fin spine goes > 5 times into standard length; diffuse black spots on sides.....	<i>Ictalurus lupus</i>

FAMILY LORICARIIDAE—suckermouth catfishes

1a. Dorsal fin short with ≤ 9 rays.....	<i>Hypostomus plecostomus</i>
1b. Dorsal fin long with ≥ 10 rays	2
2a. (1b) Light spots on a dark background	<i>Pterygoplichthys anisitsi</i>
2b. (1b) Dark spots on a light background.....	<i>Pterygoplichthys disjunctivus</i>

FAMILY SALMONIDAE—salmons

Oncorhynchus mykiss

FAMILY MUGILIDAE—mulletts

1a. Lower jaw rounded, without a symphyseal knob; lower limb of 1st gill arch with 17 to 20 gill rakers; no adipose eyelid; scales ctenoid *Agonostomus monticola*

1b. Lower jaw angular, with a prominent symphyseal knob; lower limb of 1st gill arch with 25 to 60 gill rakers; adipose eyelid well developed in adults; scales cycloid in young, ctenoid in adults *Mugil cephalus*

FAMILY ATHERINOPSIDAE—New World silversides

1a. Scales ctenoid, rough to the touch; double pairs of black spots on dorsum; bases of dorsal and anal fin covered with scales *Membras martinica*

1b. Scales cycloid, smooth to the touch; dorsum with crosshatching, but not double pairs of black spots; bases of dorsal and anal fins not covered with scales; horizontal distance between spinous dorsal and anal fin origin less than 7% of standard length
..... *Menidia audens*

FAMILY FUNDULIDAE—topminnows

1a. Distance from origin of dorsal fin to end of hypural plate < distance from origin of dorsal fin to preopercle or occasionally about equal to that distance; more than 30 longitudinal scale rows2

1b. Distance from origin of dorsal fin to end of hypural plate > distance from origin of dorsal fin to preopercle; 30 or fewer longitudinal scale rows3

2a. (1a) Body with a distinct black lateral band *Fundulus notatus*

2b. (1a) Body without a distinct black lateral band *Fundulus chrysotus*

3a. (1b) Conspicuous lateral stripe extending through eye to snout; body depth goes 4.5 to 5 times in standard length *Lucania goodei*

3b. (1b) No distinct lateral stripe; body depth goes 3.5 to 4 times in standard length *Lucania parva*

FAMILY CYPRINODONTIDAE—pupfishes

Cyprinodon variegatus

FAMILY POECILIIDAE—livebearers

- 1a. Origin of dorsal fin anterior to anal fin origin; intestinal canal long with many convolutions.....2
- 1b. Origin of dorsal fin posterior to anal fin origin; intestinal canal short with few convolutions.....5

- 2a. (1a) Teeth in single row; ventral rays of caudal fin in mature males extended to form swordlike extension *Xiphophorus hellerii*
- 2b. (1a) Teeth in villiform bands; caudal fin rays symmetrical.....3

- 3a. (2b) Dorsal fin rays < 9*Poecilia reticulata*
- 3b. (2b) Dorsal fin rays ≥104

- 4a. (3b) Dorsal fin rays 12 to 14; dorsal fin base more than ½ predorsal length; rows of dark spots on scales obscure diamond-shaped color pattern*Poecilia latipinna*
- 4b. (3b) Dorsal fin rays 10 to 12; dorsal fin base < ½ predorsal length; dark spots on scales do not obscure diamond-shaped color pattern; only exists as females.....
.....*Poecilia formosa*

- 5a. (1b) Spines at tip of 3rd anal fin ray of male gonopodium (first enlarged ray) 1 to 3 times longer than wide *Gambusia affinis*
- 5b. (1b) Spines at tip of 3rd anal fin ray of male gonopodium 4 to 10 times longer than wide.....6

- 6a. (5b) Distal segments of anterior branch of 4th fin ray of gonopodium coalesced to elbow; Extinct*Gambusia georgei*
- 6b. (5b) Distal segments of anterior branch of 4th fin ray of gonopodium not coalesced to elbow; postanal streak prominent (darker than markings on scale pockets); black markings on mouth; median row of spots on caudal fin; median row of spots on dorsal fin; terminal hook on 4th and 5th rays of gonopodium angular at tip *Gambusia geiseri*

FAMILY SYNGNATHIDAE—pipefishes

Syngnathus scovelli

FAMILY MORONIDAE—temperate basses

- 1a. Body depth goes < 3 times in standard length; teeth in single patch on back of tongue.....*Morone chrysops*
- 1b. Body depth goes > 3 times in standard length; teeth in 2 parallel patches on back of tongue.....*Morone saxatilis*

FAMILY CENTRARCHIDAE—sunfishes

- 1a. Five to 8 anal spines2
- 1b. Three anal spines.....4
- 2a. (1a) Eleven to 13 dorsal fin spines *Ambloplites rupestris*
- 2b. (1a) Six to 8 dorsal fin spines3
- 2a. (1a) Dorsal fin set back on body, length of dorsal fin base < distance from its origin to posterior margin of eye; lateral body with wide to narrow dorsal black bands; ≤ 6 dorsal spines..... *Pomoxis annularis*
- 2b. (1a) Dorsal fin set forward on body, length of dorsal fin base equal to or greater than distance from its origin to posterior margin of eye; lateral body with checkerboard black and light pattern; ≥7 dorsal spines*Pomoxis nigromaculatus*
- 4a. (1b) Body slender, body depth contained > 3 times into standard length.....5
- 4b. (1b) Body deep, body depth contained < 3 times into standard length.....8
- 5a. (4a) Dorsal fins narrowly joined at base forming a deep notch; upper jaw extends past posterior margin of eye in adults; mid-lateral stripe generally complete, rows of spots ventral to mid-lateral stripe faint and incomplete*Micropterus salmoides*
- 5b. (4a) Dorsal fins broadly joined at base forming a shallow notch; upper jaw does not reach past posterior portion of eye; bases of soft dorsal and anal fins scaled6
- 6a. (5b) No tooth patch on tongue; lower lateral region scales without black spots forming horizontal rows.....*Micropterus dolomieu*
- 6b. (5b) Tooth patch on tongue; lower lateral region scales with black spots forming horizontal rows.....7

7a. (6b) Mid-lateral stripe often appears interrupted anteriorly, rows of spots ventral to mid-lateral stripe distinct and complete.	<i>Micropterus punctulatus</i>
7b. (6b) Dark wide midlateral stripe present and disconnected anteriorly into a narrow midlateral stripe posteriorly, forming vertical bars.....	<i>Micropterus treculii</i>
8a. (4b) Teeth on tongue; head and opercle with 3 to 5 distinct dark and light longitudinal stripes; red spot on posterior margin of opercle flap in fresh specimens....	<i>Lepomis gulosus</i>
8b. (4b) No teeth on tongue; head and opercle lacking distinct dark and light longitudinal stripes	9
9a. (8b) Pectoral fins long and pointed, reach anterior portion of eye or beyond when bent forward.....	10
9b. (8b) Pectoral fins short and rounded, do not reach past eye when bent forward	12
10a. (9a) Opercle flap stiff to its margin, posterior margin either red or orange in live specimens	<i>Lepomis microlophus</i>
10b. (9a) Opercle flap flexible, posterior margin not red or orange in live specimens	11
11a. (10b) Opercle flap black to the margin; black spot on posterior base of soft dorsal fin	<i>Lepomis macrochirus</i>
11b. (10b) Opercle flap outlined with thick white band; lacking black spot on posterior base of soft dorsal fin.....	<i>Lepomis humilis</i>
12a. (9b) Black opercle flap stiff near the posterior margin with bone supporting all or majority of the flap.....	13
12b. (9b) Black opercle flap flexible near the posterior margin without bone supporting majority of the flap.....	14
13a. (12a) Body elongated with black spot on posterior base of soft dorsal fin.....	<i>Lepomis cyanellus</i>
13b. (12a) Body rounded without black spot on posterior base of soft dorsal fin; lateral body with alternating stripes formed from black and red spots.....	<i>Lepomis miniatus</i>

- 14a. (12b) Opercle flap black to the posterior margin; opercle flap is thin near the opercle bone with the narrowest width of the flexible portion of the flap about the same diameter of the eye pupil.....*Lepomis auritus*
- 14b. (12b) Opercle flap black and surrounded by white on the posterior margin; opercle flap is wide with narrowest width of the flexible flap is about two times the diameter of the eye pupil..... *Lepomis megalotis*

FAMILY PERCIDAE—perches

- 1a. Snout conical, extends beyond upper lip; body with ≥ 14 black vertical bars.....2
- 1b. Snout less conical, does not extend beyond upper lip; body with < 14 black vertical bars or with a pattern other than vertical bars.....3
- 2a. (1a) Body with thick vertical bars, bars alternate in length from long to short; 9 to 10 long bars.....*Percina carbonaria*
- 2b. (1a) Body with 14 to 16 thin vertical bars of similar length.....*Percina macrolepida*
- 3a. (1b) Sides of body with large black blotches; midline of abdomen naked or with enlarged scales4
- 3b. (1b) Sides of body without large black blotches; scales on abdomen normal5
- 4a. (3a) Upper lip connected to snout by a narrow frenum; blotches on sides of body are rectangle-shaped and bleed downward*Percina shumardi*
- 4b. (3a) Upper lip connected to snout by a broad frenum; blotches on sides of body do not bleed downward*Percina apristis*
- 5a. (3b) Lateral line short, < 6 pored scales; single row of horizontal dashes present *Etheostoma fonticola*
- 5b. (3b) Lateral line long (complete or incomplete), > 6 pored scales; if horizontal dashes present, accompanied by vertical bars6
- 6a. (5b) Lateral line arched upward *Etheostoma gracile*
- 6b. (5b) Lateral line straight.....7
- 7a. (6b) Lateral body with distinct series of M-shaped pigments; snout rounded and blunt*Etheostoma chlorosoma*

7b. (6b) Lateral body without distinct series of M-shaped pigments; snout not noticeably rounded and blunt8

8a. (7b) Anterior portion of lateral region with black horizontal dashes and posterior portion of lateral region with vertical bars; uninterrupted supratemporal canal; throat of live males orange; no reddish orange spots on sides *Etheostoma spectabile*

8b. (7b) Lateral region with vertical bars, horizontal dashes on anterior portion sometimes visible, but obscured by vertical bars; interrupted supratemporal canal; throat of live males blue or green; sides of live males scattered with reddish orange spots
.....*Etheostoma lepidum*

FAMILY SCIAENIDAE—drums

Aplodinotus grunniens

FAMILY CICHLIDAE—cichlids

1a. Anal fin spines 5 to 6*Herichthys cyanoguttatus*

1b. Anal fin spines < 5 (usually 3)..... 2

2a. (1b) Gill rakers 14 to 20 (usually 17 to 18) on lower part of first gill arch; most teeth in outer row are unicuspid in adults; sides with 3 or 4 dark blotches or with no markings; no yellow on dorsal fin; caudal fin without distinct vertical stripes
..... *Oreochromis mossambicus*

2b. (1b) Gill rakers 18 to 26 on lower part of 1st gill arch; outer row of teeth bicuspid in adults; caudal fin unmarked, or with vague, irregular dark markings, caudal fin often with a broad, red distal margin; young often with vertical bands on caudal fin
.....*Oreochromis aureus*

FAMILY ACHIRIDAE—American soles

Trinectes maculatus

NUECES RIVER BASIN

KEY TO THE FAMILIES

- 1a. Both eyes on one side of head; without right pectoral fin.. American Soles – Achiridae
- 1b. One eye on either side of head; with both pectoral fins.....2

- 1a. (1b) Body long and slender; without pelvic fins Freshwater Eels – Anguillidae
- 1b. (1b) Body truncated or elongated; with pelvic fins 2

- 3a. (2b) Caudal fin heterocercal or abbreviated heterocercal Gars – Lepiososteidae
- 3b. (2b) Caudal fin homocercal4

- 4a. (3b) One dorsal fin; pelvic fins without uniserial spines5
- 4b. (3b) One or two dorsal fins; pelvic fins with uniserial spines11

- 5a. (4a) With adipose fin.....6
- 5b. (4a) Without adipose fin8

- 6a. (5a) Without barbels.....7
- 6b. (5a) With barbels..... Bullhead Catfishes – Ictaluridae

- 7a. (6a) Scales large, < 50 lateral line scales; incisor teeth presentTetras – Characidae
- 7b. (6a) Scales small, > 60 lateral line scales; incisor teeth absent Trouts – Salmonidae

- 8a. (5b) Long anal fin with ≥ 17 fin rays Shads – Clupiedae
- 8b. (5b) Short anal fin with ≤ 13 rays9

- 9a. (8b) Caudal fin forked or emarginated; lateral line usually present.....10
- 9b. (8b) Caudal fin truncated or rounded; lateral line usually absent
..... Livebearers – Poeciliidae

10a. (9a) Inferior, fleshy mouth modified for sucking; > 7 pharyngeal teeth in main row, usually ≥ 10 dorsal fin rays	Suckers – Catostomidae
10b. (9a) Mouth usually not fleshy or modified for sucking; < 7 pharyngeal teeth in main row, usually ≤ 10 dorsal fin rays.....	Carps and Minnows – Cyprinidae
11a. (4b) Pelvic fin position abdominal or sub-thoracic; dorsal fins widely separated.....	12
11b. (4b) Pelvic fin position thoracic; dorsal fins joined or, if separate, closely adjacent to one another.....	13
12a. (11a) Dorsal fin with 4 thick spines; anal fin with 2-3 spines; adipose eyelids present	Mullets – Mugilidae
12b. (11a) Dorsal fin with 4 to 8 thin spines; anal fin with 1 spine; adipose eyelids absent	Silversides – Atherinopsidae
13a. (12b) One nostril (nare) on each side of head; lateral line interrupted	Cichlids – Cichlidae
13b. (12b) Two nostrils (nares) on each side of head; lateral line complete, incomplete, or absent	14
14a. (15b) Dorsal fin with > 23 fin rays; lateral line extends to tip of caudal fin.....	Drums – Sciaenidae
14b. (15b) Dorsal fin with < 23 fin rays; lateral line, if present, does not extend to tip of caudal fin.....	15
15a. (14b) Anal fin with 1 to 2 spines.....	Perches – Percidae
15b. (14b) Anal fin with 3 to 8 spines	16
16a. (15b) Posterior margin of operculum with a sharp spine; spiny and soft dorsal fin separate or only slightly connected; pseudobranchium present and exposed.....	Temperate Basses – Moronidae
16b. (15b) Posterior margin of operculum without a sharp spine; spiny and soft dorsal fins connected or with deep notch; pseudobranchium covered or absent.....	Sunfishes – Centrarchidae

KEY TO THE SPECIES

FAMILY LEPISOSTEIDAE—gars

- 1a. Large teeth in upper jaw in parallel rows on each side *Atractosteus spatula*
1b. Large teeth in upper jaw one row, although another non-parallel row might be present 2
- 2a. (1b) Beak long and narrow, least width goes about 12 to 20 times in length; width of beak at nostrils < eye diameter; snout > $\frac{2}{3}$ of head length *Lepisosteus osseus*
2b. (1b) Beak short and blunt, least width goes about 5 to 7 times in length; width of beak at nostrils > eye diameter; snout < $\frac{2}{3}$ of head length *Lepisosteus oculatus*

FAMILY ANGUILLIDAE—freshwater eels

Anguilla rostrata

FAMILY CLUPEIDAE—herrings

- 1a. Twenty-nine to 33 anal fin rays; mouth subterminal and below level of middle of eye; black shoulder spot $\geq$ pupil of eye *Dorosoma cepedianum*
1b. Twenty-four to 28 anal fin rays; mouth terminal and at level of eye; black shoulder spot < pupil of eye *Dorosoma petenense*

FAMILY CYPRINIDAE - minnows

- 1a. More than 15 soft rays on dorsal fin; dorsal and anal fins each with a strong serrated spine 2
1b. Fewer than 10 soft rays on dorsal fin; dorsal and anal fins without spine 3
- 2a. (1a) Upper jaw with two pairs of barbels *Cyprinus carpio*
2b. (1a) Upper jaw without barbels *Carassius auratus*
- 3a. (1b) Anal fin near caudal fin, distance from snout to origin of anal fin is > 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth with prominent parallel grooves *Ctenopharyngodon idella*
3b. (1b) Anal fin not noticeably near caudal fin: distance from snout to origin of anal fin is < 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth without prominent parallel grooves 4

4a. (3b) Intestine wound spirally around swim bladder; keratinous ridge on lower jaw	<i>Campostoma anomalum</i>
4b. (3b) Intestine not wound spirally around swim bladder; keratinous ridge of lower jaw hardly evident.....	5
5a. (4b) Abdomen behind pelvic fins with a fleshy keel lacking scales; lateral line greatly decurved, distance between anterior lateral line scale and ventral most lateral line scale is > 3 scales in height.....	<i>Notemigonus crysoleucas</i>
5b. (4b) Abdomen behind pelvic fin with scales; lateral line not greatly decurved, lateral line descends < 3 scales ventrally from highest point	6
6a. (5b) Predorsal scales appear crowded, smaller than scales on lateral body or appear as overlapping scales; black spot in the middle, anterior portion of the dorsal fin	7
6b. (5b) Predorsal scales not crowded; without black spot in the middle, anterior portion of the dorsal fin	8
7a. (6a) Caudal spot, if distinct, continuous with mid-lateral stripe; lateral line incomplete; intestine long, more than twice the standard length.....	<i>Pimephales promelas</i>
7b. (6a) Caudal spot distinct from mid-lateral stripe; lateral line complete, intestine forming a short S-shaped loop	<i>Pimephales vigilax</i>
8a. (6b) Long intestine in a flat coil.....	<i>Dionda serena</i>
8b. (6b) Short S-shaped intestine	9
9a. (8b) Moderately decurved lateral line; diamond-shaped scales; dark shoulder patch present; melanophores concentrated between rays of dorsal and anal fins	10
9b. (8b) Lateral line incomplete, complete-straight, or complete-slightly decurved; scales not noticeably diamond-shaped; without dark shoulder patch; melanophores concentrated along rays of dorsal and anal fins	12
10a. (9a) Terminal mouth	<i>Cyprinella lutrensis</i>
10b. (9a) Sub-terminal mouth	11
11a. (10b) Caudal fin base with a large black spot, about size of eye	<i>Cyprinella venusta</i>
11b. (10b) Caudal fin base without a large black spot.....	<i>Cyprinella lepida</i>

12a. (9b) Distinct and separate black dash at base of dorsal fin; apparent when viewed from above; pharyngeal teeth count usually 0,4-4,0	13
12b. (9b) No distinct and separate black dash at base of dorsal fin; pharyngeal teeth count usually 1,4-4,1 or 2,4-4,2	15
13a. (12a) Lateral line scales not markedly elevated anteriorly, scale height 1 to 2 times scale width	<i>Notropis stramineus</i>
13b. (12a) Lateral line scales markedly elevated (taller than wide) anteriorly, elevated scale height 2 to 5 times scale width.....	14
14a. (13b) Dorsal and lateral body with melanophores outlining scales; with pronounced black lateral stripe; dorsal fin height goes 2.1 or more times in pre-dorsal length; infraorbital canal complete	<i>Notropis volucellus</i>
14b. (13b) Dorsal and lateral body with sparse melanophores; scales outlined with melanophores are rare; pre-dorsal black spot is prominent and distinct from mid-dorsal stripe; dorsal fin height goes 2.0 or fewer times in pre-dorsal length; infraorbital canal incomplete.....	<i>Notropis buchanani</i>
15a. (12b) Dorsal fin origin opposite or anterior to pelvic fin origin	16
15b. (12b) Dorsal fin origin posterior to pelvic fin origin	<i>Notropis amabilis</i>
16a. (15a) Pharyngeal teeth 5-5; mouth small and almost vertical.....	<i>Opsopoeodus emiliae</i>
16b. (15a) Pharyngeal teeth are 1,4-4,1 or 2,4-4,2; mouth large and oblique	<i>Notropis texanus</i>

FAMILY CATOSTOMIDAE—suckers

1a. Dorsal fin long, base > than $\frac{1}{3}$ of standard length; 22 to 30 dorsal fin rays	2
1b. Dorsal fin short, base < than $\frac{1}{4}$ of standard length; 4 to 18 dorsal fin rays	<i>Moxostoma congestum</i>
2a. (1a) Small scales, lateral line scales > 50; eye closer to back of head than to tip of snout; head abruptly more slender than body; papillose lips.....	<i>Cycleptus elongatus</i>
2b. (1a) Large scales, lateral line scales < 45; eye closer to tip of snout than back of head; plicate lips	3

- 3a. (2b) Subopercle triangular, broadest toward base; knob present at tip of lower lip; blunt snout, forming level with eye *Carpiodes carpio*
- 3b. (2b) Subopercle semicircular, broadest towards middle; knob present at tip of lower lip; rounded snout, forming below level of eye *Ictiobus bubalus*

FAMILY CHARACIDAE—characins

Astyanax mexicanus

FAMILY ICTALURIDAE—bullhead catfishes

- 1a. Adipose fin joined to the caudal fin or separated by a shallow notch....*Noturus gyrinus*
- 1b. Adipose fin free at tip, not joined to caudal fin2
- 2a. (1b) Head dorso-ventrally compressed; mouth terminal to superior . *Pylodictis olivaris*
- 2b. (1b) Head rounded; mouth subterminal3
- 3a. (2b) Caudal fin rounded or shallowly emarginate.....4
- 3b. (2b) Caudal fin deeply forked5
- 4a. (3a) Chin barbels completely or partially black; anal fin rays 17 to 24; anal fin broadly rounded*Ameiurus melas*
- 4b. (3a) Chin barbels white or yellow; anal fin rays 24 to 27; margin of anal fin generally straight.....*Ameiurus natalis*
- 5a. (3b) Anal fin rays 30 to 36; anal fin free margin is straight; medial keel-like ridge anterior to dorsal fin forms humped back appearance*Ictalurus furcatus*
- 5b. (3b) Anal fin rays 22 to 29; anal fin free margin is rounded; no humped back appearance.....6
- 6a. (5b) Anal fin rays 27 to 29; pectoral fin spine goes < 5 times into standard length; random scattering of few black spots may be present*Ictalurus punctatus*
- 6b. (5b) Anal fin rays 22 to 26; pectoral fin spine goes > 5 times into standard length; diffuse black spots on sides..... *Ictalurus lupus*

FAMILY SALMONIDAE—salmons

Oncorhynchus mykiss

FAMILY MUGILIDAE—mulletts

- 1a. Lower jaw rounded, without a symphyseal knob; lower limb of 1st gill arch with 17 to 20 gill rakers; no adipose eyelid; scales ctenoid*Agonostomus monticola*
- 1b. Lower jaw angular, with a prominent symphyseal knob; lower limb of 1st gill arch with 25 to 60 gill rakers; adipose eyelid well developed in adults; scales cycloid in young, ctenoid in adults*Mugil cephalus*

FAMILY ATHERINOPSIDAE—New World silversides

Menidia audens

FAMILY FUNDULIDAE—topminnows

Fundulus notatus

FAMILY POECILIIDAE—livebearers

- 1a. Origin of dorsal fin anterior to anal fin origin; intestinal canal long with many convolutions2
- 1b. Origin of dorsal fin posterior to anal fin origin; intestinal canal short with few convolutions*Gambusia affinis*
- 2a. (1a) Dorsal fin rays 12 to 14; dorsal fin base more than $\frac{1}{2}$ predorsal length; rows of dark spots on scales obscure diamond-shaped color pattern*Poecilia latipinna*
- 2b. (1a) Dorsal fin rays 10 to 12; dorsal fin base $< \frac{1}{2}$ predorsal length; dark spots on scales do not obscure diamond-shaped color pattern; only exists as females.....
.....*Poecilia formosa*

FAMILY MORONIDAE—temperate basses

- 1a. Body depth goes < 3 times in standard length; teeth in single patch on back of tongue.....*Morone chrysops*
- 1b. Body depth goes > 3 times in standard length; teeth in 2 parallel patches on back of tongue.....*Morone saxatilis*

FAMILY CENTRARCHIDAE—sunfishes

- 1a. Five to 8 anal spines2
- 1b. Three anal spines.....3

- 2a. (1a) Dorsal fin set back on body, length of dorsal fin base < distance from its origin to posterior margin of eye; lateral body with wide to narrow dorsal black bands; ≤ 6 dorsal spines..... *Pomoxis annularis*
- 2b. (1a) Dorsal fin set forward on body, length of dorsal fin base equal to or greater than distance from its origin to posterior margin of eye; lateral body with checkerboard black and light pattern; ≥ 7 dorsal spines *Pomoxis nigromaculatus*
- 3a. (1b) Body slender, body depth contained > 3 times into standard length.....4
- 3b. (1b) Body deep, body depth contained < 3 times into standard length.....6
- 4a. (3a) Dorsal fins narrowly joined at base forming a deep notch; upper jaw extends past posterior margin of eye in adults; mid-lateral stripe generally complete, rows of spots ventral to mid-lateral stripe faint and incomplete *Micropterus salmoides*
- 4b. (3a) Dorsal fins broadly joined at base forming a shallow notch; upper jaw does not reach past posterior portion of eye; bases of soft dorsal and anal fins scaled5
- 5a. (4b) No tooth patch on tongue; lower lateral region scales without black spots forming horizontal rows..... *Micropterus dolomieu*
- 5b. (4b) Tooth patch on tongue; lower lateral region scales with black spots forming horizontal rows..... *Micropterus treculii*
- 6a. (3b) Teeth on tongue; head and opercle with 3 to 5 distinct dark and light longitudinal stripes; red spot on posterior margin of opercle flap in fresh specimens.... *Lepomis gulosus*
- 6b. (3b) No teeth on tongue; head and opercle lacking distinct dark and light longitudinal stripes7
- 7a. (6b) Pectoral fins long and pointed, reach anterior portion of eye or beyond when bent forward.....8
- 7b. (6b) Pectoral fins short and rounded, do not reach past eye when bent forward.....10
- 8a. (7a) Opercle flap stiff to its margin, posterior margin either red or orange in live specimens *Lepomis microlophus*
- 8b. (7a) Opercle flap flexible, posterior margin not red or orange in live specimens9

- 9a. (8b) Opercle flap black to the margin; black spot on posterior base of soft dorsal fin *Lepomis macrochirus*
- 9b. (8b) Opercle flap outlined with thick white band; lacking black spot on posterior base of soft dorsal fin *Lepomis humilis*
- 10a. (7b) Black opercle flap stiff near the posterior margin with bone supporting all or majority of the flap 11
- 10b. (7b) Black opercle flap flexible near the posterior margin without bone supporting majority of the flap 12
- 11a. (10a) Body elongated with black spot on posterior base of soft dorsal fin
..... *Lepomis cyanellus*
- 11b. (10a) Body rounded without black spot on posterior base of soft dorsal fin; lateral body with alternating stripes formed from black and red spots *Lepomis miniatus*
- 12a. (10b) Opercle flap black to the posterior margin; opercle flap is thin near the opercle bone with the narrowest width of the flexible portion of the flap about the same diameter of the eye pupil *Lepomis auritus*
- 12b. (10b) Opercle flap black and surrounded by white on the posterior margin; opercle flap is wide with narrowest width of the flexible flap is about two times the diameter of the eye pupil *Lepomis megalotis*

FAMILY PERCIDAE—perches

- 1a. Snout conical, extends beyond upper lip; body with ≥ 14 black vertical bars; bars contain medial constrictions, giving them an hourglass shape *Percina carbonaria*
- 1b. Snout less conical, does not extend beyond upper lip; body with < 14 black vertical bars or with a pattern other than vertical bars 2
- 2a. (1b) Lateral line arched upward; lateral region may contain verticle 8-10 green vertical bars *Etheostoma gracile*
- 2b. (1b) Lateral line straight; lateral region with 8 to 13 vertical bars . *Etheostoma lepidum*

FAMILY SCIAENIDAE—drums

Aplodinotus grunniens

FAMILY CICHLIDAE—cichlids

1a. Anal fin spines 5 to 6*Herichthys cyanoguttatus*

1b. Anal fin spines < 5 (usually 3)..... 2

2a. (1b) Gill rakers 14 to 20 (usually 17 to 18) on lower part of first gill arch; most teeth in outer row are unicuspid in adults; sides with 3 or 4 dark blotches or with no markings; no yellow on dorsal fin; caudal fin without distinct vertical stripes

..... *Oreochromis mossambicus*

2b. (1b) Gill rakers 18 to 26 on lower part of 1st gill arch; outer row of teeth bicuspid in adults; caudal fin unmarked, or with vague, irregular dark markings, caudal fin often with a broad, red distal margin; young often with vertical bands on caudal fin

.....*Oreochromis aureus*

FAMILY ACHIRIDAE—American soles

Trinectes maculatus

RED RIVER BASIN

KEY TO THE FAMILIES

- 1a. Jawless, disc-shaped mouth; without pectoral and pelvic fins; 7 pairs of external gill openings Lampreys – Petromyzontidae
- 1b. Jawed mouth; one gill opening on each side of head; with pectoral, pelvic, or both fins.....2

- 2a. (1b) Body long and slender; without pelvic fins Freshwater Eels – Anguillidae
- 2b. (1b) Body truncated or elongated; with pelvic fins 3

- 3a. (2b) Caudal fin heterocercal or abbreviated heterocercal4
- 3b. (2b) Caudal fin homocercal7

- 4a. (3a) Caudal fin heterocercal, body with bony scutes or appears scaleless.....5
- 4b. (3a) Caudal fin abbreviated heterocercal; body with ganoid or cycloid scales6

- 5a. (4a) Long, paddle shaped snout; scaleless, except for a few ganoid scales at the base of caudal fin Paddlefishes – Polyodontidae
- 5b. (4a) Snout conical or shovel-shaped with four barbels on ventral surface; several rows of bony scutes (plates) along body.....Sturgeons – Acipenseridae

- 6a. (4b) Body covered with ganoid scales; snout formed into a beak; without gular plate..... Gars – Lepisosteidae
- 6b. (4b) Body covered with cycloid scales, snout not formed into a beak, with a gular plate.....Bowfin – Amiidae

- 7a. (3b) Jaws duckbilled Pickerels – Esocidae
- 7b. (3b) Jaws not duckbilled8

- 8a. (7b) One dorsal fin; pelvic fins without uniserial spines9
- 8b. (7b) One or two dorsal fins; pelvic fins with uniserial spines18

9a. (8a) With adipose fin.....	10
9b. (8a) Without adipose fin	12
10a. (9a) Without barbels.....	11
10b. (9a) With barbels.....	Bullhead Catfishes – Ictaluridae
11a. (10a) Scales large, < 50 lateral line scales; incisor teeth present ...	Tetras – Characidae
11b. (10a) Scales small, > 60 lateral line scales; incisor teeth absent .	Trouts – Salmonidae
12a. (9b) Long anal fin with ≥ 17 fin rays	13
12b. (9b) Short anal fin with ≤ 13 rays	14
13a. (12a) Belly with scales forming a saw-like keel	Shads – Clupiedae
13b. (12a) Belly without scales forming a saw-like keel.....	Mooneyes – Hiodontidae
14a. (12b) Caudal fin forked or emarginated; lateral line usually present.....	15
14b. (12b) Caudal fin truncated or rounded; lateral line usually absent	16
15a. (14a) Inferior, fleshy mouth modified for sucking; > 7 pharyngeal teeth in main row, usually ≥ 10 dorsal fin rays	Suckers – Catostomidae
15b. (14a) Mouth usually not fleshy or modified for sucking; < 7 pharyngeal teeth in main row, usually ≤ 10 dorsal fin rays.....	Carp and Minnows – Cyprinidae
16a. (14b) Mature males with rounded anal fin; males and females with 3rd anal fin ray branched, no gonopodium present	17
16b. (14b) Mature males with pointed anal fin forming a gonopodium; males and females with 3rd anal fin ray unbranched.	Livebearers – Poeciliidae
17a. (16a) Body robust; teeth in single row are incisor-like and tricuspid (three points on a tooth).	Pupfishes – Cyprinodontidae
17b. (16a) Body elongate; conical (cone-shaped) pointed teeth in a single row or several rows.....	Killifishes – Fundulidae

18a. (8b) Anus anterior to pelvic fins; > 5 soft rays on each pelvic fin.....	
.....	Pirate Perch – Aphredoderidae
18b. (8b) Anus posterior to pelvic fins; 5 soft rays on pelvic fins.....	19
19a. (18b) Pelvic fin position abdominal or sub-thoracic; dorsal fins widely separated...	20
19b. (18b) Pelvic fin position thoracic; dorsal fins joined or, if separate, closely adjacent to one another.....	21
20a. (19a) Dorsal fin with 4 thick spines; anal fin with 2-3 spines; adipose eyelids present	Mullets – Mugilidae
20b. (19a) Dorsal fin with 4 to 8 thin spines; anal fin with 1 spine; adipose eyelids absent	Silversides – Atherinopsidae
21a. (19b) Dorsal fin with > 23 fin rays; lateral line extends to tip of caudal fin.....	
.....	Drums – Sciaenidae
21b. (19b) Dorsal fin with < 23 fin rays; lateral line, if present, does not extend to tip of caudal fin.....	22
22a. (21b) Anal fin with 1 to 2 spines.....	Perches – Percidae
22b. (21b) Anal fin with 3 to 8 spines	23
23a. (22b) Posterior margin of operculum with a sharp spine; spiny and soft dorsal fin separate or only slightly connected; pseudobranchium present and exposed.....	
.....	Temperate Basses – Moronidae
23b. (22b) Posterior margin of operculum without a sharp spine; spiny and soft dorsal fins connected or with deep notch; pseudobranchium covered or absent.....	24
24a. (23b) Lateral line present or incomplete	Sunfishes – Centrarchidae
24b. (23b) Lateral line absent	Pygmy Sunfishes – Eleotridae

KEY TO THE SPECIES

FAMILY PETROMYZONTIDAE – lampreys

- 1a. Disc-shaped mouth large, diameter of mouth $>$ body width and about 140 times into total length; with rasping teeth; adults with well-developed intestine.....
.....*Ichthyomyzon castaneus*
- 1b. Disc-shaped mouth small, diameter of mouth $\leq$ body width and about 170 to 250 times into total length; without rasping teeth; adults without well-developed intestine *Ichthyomyzon gagei*

FAMILY ACIPENSERIDAE—sturgeons

Scaphirhynchus platyrhynchus

FAMILY POLYDONTIDAE—paddlefishes

Polyodon spathula

FAMILY LEPISOSTEIDAE—gars

- 1a. Large teeth in upper jaw in parallel rows on each side*Atractosteus spatula*
- 1b. Large teeth in upper jaw one row, although another non-parallel row might be present2
- 2a. (1b) Beak long and narrow, least width goes about 12 to 20 times in length; width of beak at nostrils $<$ eye diameter; snout $>$ $\frac{2}{3}$ of head length..... *Lepisosteus osseus*
- 2b. (1b) Beak short and blunt, least width goes about 5 to 7 times in length; width of beak at nostrils $>$ eye diameter; snout $<$ $\frac{2}{3}$ of head length3
- 3a. (2b) Fifty-nine to 63 lateral line scales; 38 to 44 scale rows around body, lacking black spots on head*Lepisosteus platostomus*
- 3b. (2b) Fifty-four to 57 lateral line scales; 32 to 38 scale rows around body; with black spots on head..... *Lepisosteus oculatus*

FAMILY AMIIDAE—bowfins

Amia calva

FAMILY HIODONTIDAE—mooneyes

Hiodon alosoides

FAMILY ANGUILLIDAE—freshwater eels

Anguilla rostrata

FAMILY CLUPEIDAE—herrings

- 1a. Twenty-nine to 33 anal fin rays; mouth subterminal and below level of middle of eye; black shoulder spot $\geq$ pupil of eye *Dorosoma cepedianum*
- 1b. Twenty-four to 28 anal fin rays; mouth terminal and at level of eye; black shoulder spot $<$ pupil of eye *Dorosoma petenense*

FAMILY CYPRINIDAE - minnows

- 1a. More than 15 soft rays on dorsal fin; dorsal and anal fins each with a strong serrated spine2
- 1b. Fewer than 10 soft rays on dorsal fin; dorsal and anal fins without spine.....3
- 2a. (1a) Upper jaw with two pairs of barbels..... *Cyprinus carpio*
- 2b. (1a) Upper jaw without barbels..... *Carassius auratus*
- 3a. (1b) Middle of eye is noticeably low on head, ventral to head
midline *Hypophthalmichthys nobilis*
- 3b. (1b) Middle of eye is not noticeably low on head, equal or dorsal to head midline.....4
- 4a. (3b) Anal fin near caudal fin, distance from snout to origin of anal fin is > 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth with prominent parallel grooves *Ctenopharyngodon idella*
- 4b. (3b) Anal fin not noticeably near caudal fin: distance from snout to origin of anal fin is < 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth without prominent parallel grooves5
- 5a. (4b) Intestine wound spirally around swim bladder; keratinous ridge on lower jaw
..... *Camptostoma anomalum*
- 5b. (4b) Intestine not wound spirally around swim bladder; keratinous ridge of lower jaw hardly evident.....6

6a. (5b) Abdomen behind pelvic fins with a fleshy keel lacking scales; lateral line greatly decurved, distance between anterior lateral line scale and ventral most lateral line scale is > 3 scales in height.....	<i>Notemigonus crysoleucas</i>
6b. (5b) Abdomen behind pelvic fin with scales; lateral line not greatly decurved, lateral line descends < 3 scales ventrally from highest point	7
7a. (6b) With maxillary barbels, might be small and not observable without opening the mouth or with magnification.....	8
7b. (6b) Without maxillary barbels	11
8a. (7a) Mouth terminal; distinct black spot located anteriorly on dorsal fin; pharyngeal teeth on main row 5-4 or 5-5.....	<i>Semotilus atromaculatus</i>
8b. (7a) Mouth subterminal or inferior; no distinct black spot on dorsal fin; pharyngeal teeth on main row 4-4	9
9a. (8b) Body silvery, without scattered black specks.....	<i>Macrhybopsis storeriana</i>
9b. (8b) Body with scattered black specks.....	10
10a. (9b) Two pairs of barbels; posterior barbels longer than orbit length; anterior barbels usually half of orbit length.....	<i>Macrhybopsis australis</i>
10b. (9b) One or 2 pairs of barbels; posterior barbels less than orbit length; anterior barbels, if present, < half of posterior barbel length	<i>Macrhybopsis hyostoma</i>
11a. (7b) Thick lower lip at corners, mouth noticeably ventral; black spot at base of caudal fin.....	<i>Phenacobius mirabilis</i>
11b. (7b) Lower lip thin or not noticeably thick; with or without black spot at base of caudal fin	12
12a. (11b) Predorsal scales appear crowded, smaller than scales on lateral body or appear as overlapping scales; black spot in the middle, anterior portion of the dorsal fin.....	13
12b. (11b) Predorsal scales not crowded; without black spot in the middle, anterior portion of the dorsal fin.....	14
13a. (12a) Caudal spot, if distinct, continuous with mid-lateral stripe; lateral line incomplete; intestine long, more than twice the standard length.....	<i>Pimephales promelas</i>
13b. (12a) Caudal spot distinct from mid-lateral stripe; lateral line complete, intestine forming a short S-shaped loop	<i>Pimephales vigilax</i>

14a. (12b) Long intestine in a flat coil	15
14b. (12b) Short S-shaped intestine	17
15a. (14a) Terminal mouth; scales are diamond-shaped, most noticeable dorsally.....	<i>Hybognathus hayi</i>
15b. (14a) Sub-terminal mouth; scales not diamond-shaped.....	16
16a. (15b) Head width greater than distance from tip of snout to posterior margin of orbital; internal posterior basioccipital process is narrow and peg-like, width of internal posterior basioccipital process fits in to head width at occipital > 7 times.....	<i>Hybognathus placitus</i>
16b. (15b) Head width about equal to distance from tip of snout to posterior margin of orbital; internal posterior basioccipital process is wide and flat, width of internal posterior basioccipital process fits in to head width at occipital < 7 times.....	<i>Hybognathus nuchalis</i>
17a. (14b) Moderately decurved lateral line; diamond-shaped scales; dark shoulder patch present; melanophores concentrated between rays of dorsal and anal fins	18
17b. (14b) Lateral line incomplete, complete-straight, or complete-slightly decurved; scales not noticeably diamond-shaped; without dark shoulder patch; melanophores concentrated along rays of dorsal and anal fins	19
18a. (17a) Caudal fin base with a large black spot, about size of eye ...	<i>Cyprinella venusta</i>
18b. (17a) Caudal fin base without a large black spot.....	<i>Cyprinella lutrensis</i>
19a. (17b) Lateral line incomplete, < 11 pored scales	20
19b. (17b) Lateral line complete or mostly complete, > 11 pored scales	21
20a. (19a) Mouth terminal and oblique; dorsal fin origin posterior to pelvic fin origin; lacking smaller black spots above or below black spot at base of caudal fin	<i>Pteronotropis hubbsi</i>
20b. (19a) Mouth sub-terminal and horizontal; dorsal fin origin in line with pelvic fin origin with smaller black spots above and below black spot at base of caudal fin.....	<i>Notropis maculatus</i>

21a. (19b) Distinct and separate black dash at base of dorsal fin; apparent when viewed from above; pharyngeal teeth count usually 0,4-4,0.....	22
21b. (19b) No distinct and separate black dash at base of dorsal fin; pharyngeal teeth count usually 1,4-4,1 or 2,4-4,2	25
22a. (21a) Lateral line scales markedly elevated (taller than wide) anteriorly, elevated scale height 2 to 5 times scale width.....	23
22b. (21a) Lateral line scales not markedly elevated anteriorly, scale height 1 to 2 times scale width	24
23a. (22a) Dorsal and lateral body with melanophores outlining scales; with pronounced black lateral stripe; dorsal fin height goes 2.1 or more times in pre-dorsal length; infraorbital canal complete	<i>Notropis volucellus</i>
23b. (22a) Dorsal and lateral body with sparse melanophores; scales outlined with melanophores are rare; pre-dorsal black spot is prominent and distinct from mid-dorsal stripe; dorsal fin height goes 2.0 or fewer times in pre-dorsal length; infraorbital canal incomplete	<i>Notropis buchanani</i>
24a. (22b) Eye large, eye diameter is > snout length.....	<i>Notropis stramineus</i>
24b. (22b) Eye small, eye diameter is < snout length.....	<i>Notropis bairdi</i>
25a. (21b) Exposed portions of lateral line scales greatly elevated (taller than wide), elevated scale height 2 to 5 times scale width; dorsal scales with dark marking forming longitudinal stripes.....	<i>Luxilus chrysocephalus</i>
25b. (21b) Lateral line scales not elevated, scale height 1 to 2 times scale width; dorsal scales to not form longitudinal stripes	26
26a. (25b) Depressed dorsal fin longer than head.....	<i>Hybopsis amnis</i>
26b. (25b) Depressed dorsal fin shorter than head	27
27a. (26b) Mouth is sub-terminal; pharyngeal teeth are 0,4-4,0.....	<i>Notropis atrocaudalis</i>
27b. (26b) Mouth is terminal; pharyngeal teeth are 1,4-4,1 or 2,4-4,2 or 5-5	28
28a. (27b) Dorsal fin origin opposite or anterior to pelvic fin origin	29
28b. (27b) Dorsal fin origin posterior to pelvic fin origin	34

29a. (28a) Prominent mid-lateral stripe, extending through eye	30
29b. (28a) No prominent mid-lateral stripe present.....	32
30a. (29a) Pharyngeal teeth 5-5; mouth small and almost vertical.....	<i>Opsopoeodus emiliae</i>
30b. (29a) Pharyngeal teeth are 1,4-4,1 or 2,4-4,2; mouth large and oblique	31
31a. (30b) Usually 8 anal fin rays; inside of mouth with black melanophores; dorsal fin insertion is opposite to pelvic fin insertion	<i>Notropis chalybaeus</i>
31b. (30b) Usually 7 anal fin rays; inside of mouth without black melanophores; dorsal fin insertion is anterior to pelvic fin insertion.....	<i>Notropis texanus</i>
32a. (29b) Usually 8 anal fin rays; head is narrow, depth at occiput more than width at occiput	<i>Notropis shumardi</i>
32b. (29b) Usually 7 anal fin rays; head is wide, depth at occiput less than or equal to width at occiput.....	33
33a. (32b) Mid-dorsal stripe about 5 chromatophores wide; snout overhanging mouth; middle portion of upper jaw narrower than ends	<i>Notropis potteri</i>
33b. (32b) Mid-dorsal stripe about 10 chromatophores wide; snout not overhanging mouth; middle portion of upper jaw is about the same width as the ends	<i>Notropis blennioides</i>
34a. (28b) Small scales, ≥ 41 lateral line scales, > 25 predorsal scales.....	35
34b. (28b) Moderate-sized scales, ≤ 40 lateral line scales, < 24 predorsal scales	<i>Notropis atherinoides</i>
35a. (34a) Dorsal fin with black melanophores extending from mid-dorsal stripe into the anterior fin ray; edges of the anterior dorsolateral scales are outlined with black melanophores, producing chevron pattern.	<i>Lythrurus umbratilis</i>
35b. (34a) Dorsal fin with black melanophores not extending from mid-dorsal stripe into the anterior fin ray, lacks chevron pattern	<i>Lythrurus fumeus</i>

FAMILY CATOSTOMIDAE—suckers

1a. Dorsal fin long, base $>$ than $\frac{1}{3}$ of standard length; 22 to 30 dorsal fin rays	2
1b. Dorsal fin short, base $<$ than $\frac{1}{4}$ of standard length; 4 to 18 dorsal fin rays	6

- 2a. (1a) Small scales, lateral line scales > 50; eye closer to back of head than to tip of snout; head abruptly more slender than body; papillose lips..... *Cycleptus elongatus*
- 2b. (1a) Large scales, lateral line scales < 45; eye closer to tip of snout than back of head; plicate lips3
- 3a. (2b) Subopercle triangular, broadest toward base; knob present at tip of lower lip; blunt snout, forming level with eye *Carpiodes carpio*
- 3b. (2b) Subopercle semicircular, broadest towards middle; knob absent at tip of lower lip; rounded snout, forming below level of eye4
- 4a. (3b) Mouth large and oblique; upper jaw length is equal to snout length.....
.....*Ictiobus cyprinellus*
- 4b. (3b) Mouth small and nearly horizontal; upper jaw shorter than snout5
- 5a. (4b) Body elongate and slender, greatest body depth goes 2.6 to 3.3 times in standard length, and height of anterior rays in dorsal and anal fins often less than 2/3 head length in individuals >300 mm; small eye, eye diameter goes ≥ 2 times in snout length of individuals <300 mm *Ictiobus niger*
- 5b. (4b) Body deep and narrow, greatest body depth goes 2.2 to 2.8 times in standard length, and height of anterior dorsal and anal fin rays often greater than 2/3 head length in individuals >300 mm; large eye, eye diameter goes ≤ 2 times in snout length of individuals <300 mm *Ictiobus bubalus*
- 6a. (1b) Lateral line complete and well developed; air bladder with 3 chambers *Moxostoma erythrurum*
- 6b. (1b) Lateral line incomplete or absent; air bladder with 2 chambers7
- 7a. (6b) Lateral line incomplete; rows of spots.....*Minytrema melanops*
- 7b. (6b) Lateral line absent8
- 8a. (7b) Scales larger, lateral scale count 34 to 37; eye larger, eye length $\frac{1}{2}$ of snout length; dorsal fin rays 11 or 12; back with crescentic scale marks.....*Erimyzon sucetta*
- 8b. (7b) Scales smaller, lateral scale count 39 to 43; eye smaller, eye length < $\frac{1}{2}$ of snout length); dorsal fin rays 9 or 10; back without crescentic scale marks *Erimyzon claviformis*

FAMILY CHARACIDAE—characins

Astyanax mexicanus

FAMILY ICTALURIDAE—bullhead catfishes

- 1a. Adipose fin joined to the caudal fin or separated by a shallow notch.....2
- 1b. Adipose fin free at tip, not joined to caudal fin3

- 2a. (1a) Mouth terminal; pectoral fin spine not serrated; lower lip and chin not heavily speckled with black pigment.....*Noturus gyrinus*
- 2b. (1a) Mouth sub-terminal; pectoral spine serrated; lower lip and chin heavily speckled with black pigment.....*Noturus nocturnus*

- 3a. (1b) Head dorso-ventrally compressed; mouth terminal to superior . *Pylodictis olivaris*
- 3b. (1b) Head rounded; mouth subterminal4

- 4a. (3b) Caudal fin rounded or shallowly emarginate.....5
- 4b. (3b) Caudal fin deeply forked7

- 5a. (4a) Chin barbels white or yellow; anal fin rays 24 to 27; margin of anal fin generally straight.....*Ameiurus natalis*
- 5b. (4a) Chin barbels completely or partially black; anal fin rays 17 to 24; anal fin broadly rounded6

- 6a. (5b) Posterior margin of pectoral fin spine nearly smooth; anal fin rays 17 to 23; dorsal and lateral body uniformly dark.....*Ameiurus melas*
- 6b. (5b) Posterior margin of pectoral fin spine with serrations; anal fin rays 21 to 24; dorsal and lateral body mottled.....*Ameiurus nebulosus*

- 7a. (4b) Anal fin rays 30 to 36; anal fin free margin is straight; medial keel-like ridge anterior to dorsal fin forms humped back appearance*Ictalurus furcatus*
- 7b. (4b) Anal fin rays 22 to 29; anal fin free margin is rounded; no humped back appearance.....*Ictalurus punctatus*

FAMILY SALMONIDAE—salmons

Oncorhynchus mykiss

FAMILY ESOCIDAE—pikes and pickerels

1a. Snout short, distance from tip of snout to center of eye $\leq$ distance from center of eye to rear margin of operculum; < 115 scale rows along body *Esox americanus*

1b. Snout long, distance from tip of snout to center of eye > distance from center of eye to rear margin of operculum; > 120 scale rows along body *Esox niger*

FAMILY APHREDODERIDAE—pirate perch

Aphredoderus sayanus

FAMILY MUGILIDAE—mulletts

Mugil cephalus

FAMILY ATHERINOPSIDAE—New World silversides

1a. Scales small, > 60 scales in lateral series, jaws produced into a short beak; snout length > eye length; > 20 anal fin rays..... *Labidesthes sicculus*

1b. Scales large, < 50 scales in lateral series; jaws not produced into a beak; snout length $\leq$ eye length; < 20 anal fin rays..... *Menidia audens*

FAMILY FUNDULIDAE—topminnows

1a. Lateral body with 15 to 17 prominent dark bars alternating with near equal width bands of white or yellow bars, dark bars less distinct in females; small scales, usually > 40 scales along lateral row *Fundulus zebrinus*

1b. Lateral body without 15 to 17 prominent dark bars, with spots or a prominent mid-lateral stripe; large scales, usually < 40 scales along lateral row.....2

2a. (1b) Body with a distinct black lateral band3

2b. (1b) Body without a distinct black lateral band4

3a. (2a) Distinct black spots on anterior dorso-lateral region are as pronounced as lateral stripe; distinct black spots throughout dorsal and caudal fins *Fundulus olivaceus*

3b. (2a) Faint black spots on anterior dorso-lateral region are not as pronounced as lateral stripe; distinct black spots near base of dorsal and caudal fins..... *Fundulus notatus*

- 4a. (2b) Dorsal fin originating anterior to anal fin origin; more than 15 scale rows from pelvic fin origin to isthmus predorsal stripe absent or not reaching occiput
..... *Fundulus grandis*
- 4b. (2b) Dorsal fin originating posterior to anal fin origin5
- 5a. (4b) Red to dark spots in multiple rows longitudinally along lateral sides; usually with dark subocular bar *Fundulus blairae*
- 5b. (4b) Body mottled, barred or irregularly spotted; no dark subocular bar
..... *Fundulus chrysotus*

FAMILY CYPRINODONTIDAE—pupfishes

Cyprinodon rubrofluviatilis

FAMILY POECILIIDAE—livebearers

Gambusia affinis

FAMILY MORONIDAE—temperate basses

- 1a. Dorsal fins united at base; 2nd and 3rd anal fin spines approximately equal in length; no teeth on tongue; 9 to 10 anal fin soft rays; stripes along sides usually sharply broken and offset above front of anal fin *Morone mississippiensis*
- 1b. Dorsal fins separated; 2nd anal fin spine much shorter than 3rd; base of tongue with teeth; 11 to 13 anal fin soft rays; stripes along sides usually continuous2
- 2a. (1b) Body depth goes < 3 times in standard length; teeth in single patch on back of tongue..... *Morone chrysops*
- 2b. (1b) Body depth goes > 3 times in standard length; teeth in 2 parallel patches on back of tongue *Morone saxatilis*

FAMILY CENTRARCHIDAE—sunfishes

- 1a. Five to 8 anal spines2
- 1b. Three anal spines4
- 2a. (1a) Eleven to 13 dorsal fin spines *Centrarchus macropterus*
- 2b. (1a) Six to 8 dorsal fin spines3

- 3a. (2b) Dorsal fin set back on body, length of dorsal fin base < distance from its origin to posterior margin of eye; lateral body with wide to narrow dorsal black bands; ≤ 6 dorsal spines..... *Pomoxis annularis*
- 3b. (2b) Dorsal fin set forward on body, length of dorsal fin base equal to or greater than distance from its origin to posterior margin of eye; lateral body with checkerboard black and light pattern; ≥ 7 dorsal spines*Pomoxis nigromaculatus*
- 4a. (1b) Body slender, body depth contained > 3 times into standard length.....5
- 4b. (1b) Body deep, body depth contained < 3 times into standard length.....7
- 5a. (4a) Dorsal fins narrowly joined at base forming a deep notch; upper jaw extends past posterior margin of eye in adults; mid-lateral stripe generally complete, rows of spots ventral to mid-lateral stripe faint and incomplete*Micropterus salmoides*
- 5b. (4a) Dorsal fins broadly joined at base forming a shallow notch; upper jaw does not reach past posterior portion of eye; bases of soft dorsal and anal fins scaled6
- 6a. (5b) No tooth patch on tongue; lower lateral region scales without black spots forming horizontal rows.....*Micropterus dolomieu*
- 6b. (5b) Tooth patch on tongue; lower lateral region scales with black spots forming horizontal rows.....*Micropterus punctulatus*
- 7a. (4b) Teeth on tongue; head and opercle with 3 to 5 distinct dark longitudinal stripes; red spot on posterior margin of opercle flap in fresh specimens*Lepomis gulosus*
- 7b. (4b) No teeth on tongue; head and opercle lacking distinct dark longitudinal stripes8
- 8a. (7b) Pectoral fins long and pointed, extending past anterior portion of eye or when bent forward9
- 8b. (7b) Pectoral fins short and rounded, do not extend past eye when bent forward11
- 9a. (7a) Opercle flap stiff to its margin, posterior margin either red or orange in live specimens*Lepomis microlophus*
- 9b. (7a) Opercle flap flexible, posterior margin not red or orange in live specimens10
- 10a. (9b) Opercle flap black to the margin; black spot on posterior base of soft dorsal fin*Lepomis macrochirus*
- 10b. (9b) Opercle flap outlined with thin white band; lacking black spot on posterior base of soft dorsal fin..... *Lepomis humilis*

11a. (8b) Black opercle flap stiff near the posterior margin with bone supporting all or majority of the flap.....	12
11b. (8b) Black opercle flap flexible near the posterior margin without bone supporting majority of the flap.....	14
12a. (11a) Lateral line incomplete; smaller individuals with black spot surrounded by white margin on posterior base of soft dorsal fin	<i>Lepomis symmetricus</i>
12b. (11a) Lateral line complete; black spot, if present, on posterior base of soft dorsal fin without white margin	13
13a. (12b) Body elongated with black spot on posterior base of soft dorsal fin.....	<i>Lepomis cyanellus</i>
13b. (12b) Body rounded without black spot on posterior base of soft dorsal fin; lateral body with alternating stripes formed from black and red spots.....	<i>Lepomis miniatus</i>
14a. (11b) Opercle flap black to the posterior margin; opercle flap is thin near the opercle bone with the narrowest width of the flexible portion of the flap about the same diameter of the eye pupil.....	<i>Lepomis auritus</i>
14b. (11b) Opercle flap black and surrounded by white on the posterior margin; opercle flap is wide with narrowest width of the flexible flap is about two times the diameter of the eye pupil.....	15
15a. (14b) Twelve pectoral fin rays, 3 to 5 cheek scales; opercle flap often with white pigment form speckles, distinct red spots (white in preserved specimens) along lateral line.....	<i>Lepomis marginatus</i>
15b. (14b) Thirteen to 15 pectoral fin rays, 5 to 7 cheek scales; opercle flaps with red or white margin; 13 to 15 pectoral fin rays	<i>Lepomis megalotis</i>

FAMILY PERCIDAE—perches

1a. Body depth contained in standard length more than 7 times	2
1b. Body depth contained in standard length less than 7 times	3
2a. (1a) Lateral blotches longer than deep	<i>Ammocrypta clara</i>
2b. (1a) Lateral blotches deeper than long.....	<i>Ammocrypta vivax</i>

3a. (1b) Snout conical, extends beyond upper lip; body with ≥ 14 black vertical bars	4
3b. (1b) Snout less conical, does not extend beyond upper lip; body with < 14 black vertical bars or with a pattern other than vertical bars.....	5
4a. (3a) Body with 14 to 16 thin vertical bars of similar length	<i>Percina macrolepida</i>
4b. (3a) Body with thick vertical bars, bars alternate in length from long to short	<i>Percina caprodes</i>
5a. (3b) Sides of body with large black blotches; midline of abdomen naked or with enlarged scales	6
5b. (3b) Sides of body without large black blotches; scales on abdomen normal	9
6a. (5a) Upper lip connected to snout by a narrow frenum; blotches on sides of body are rectangle-shaped and bleed downward	<i>Percina shumardi</i>
6b. (5a) Upper lip connected to snout by a broad frenum; blotches on sides of body do not bleed downward	7
7a. (6b) Nape unscaled; blotches on sides of body are rectangle shaped and might appear connected	<i>Percina maculata</i>
7b. (6b) Nape scaled; blotches on sides of body not rectangle shaped	8
8a. (7b) Sides of body with large, black heart-shaped blotches; preopercle with ≥ 5 serrations	<i>Percina sciera</i>
8b. (7b) Sides of body with large diamond-shaped blotches; preopercle with 0 to 3 serrations	<i>Percina phoxocephala</i>
9a. (5b) Lateral line short, < 6 pored lateral line scales; single row of horizontal dashes present	<i>Etheostoma proeliare</i>
9b. (5b) Lateral line long, > 6 pored lateral line scales; if horizontal dashes present, accompanied by vertical bars.....	10
10a. (9b) Pectoral fin long, pectoral fin folded forward extends past head	<i>Etheostoma histrio</i>
10b. (9b) Pectoral fin short, pectoral fin folded forward does not extend past.....	11

11a. (10b) Lateral line arched upward	12
11b. (10b) Lateral line straight.....	13
12a. (11a) Breast without scales; breast and abdomen without black speckles.....	
.....	<i>Etheostoma gracile</i>
12b. (11a) Breast with scales; breast and abdomen with black speckles.....	
.....	<i>Etheostoma fusiforme</i>
13a. (11b) Lateral body with distinct series of M-shaped pigments; snout rounded and blunt	<i>Etheostoma chlorosoma</i>
13b. (11b) Lateral body without distinct series of M-shaped pigments; snout not noticeably rounded and blunt.....	14
14a. (13b) Lateral region with mottling bisected by a light colored lateral stripe.....	<i>Etheostoma parvipinne</i>
14b. (13b) Lateral region without mottling bisected by a light colored lateral stripe	15
15a. (14b) Gill membranes widely joined across isthmus	16
15b. (14b) Gill membranes either not joined or barely joined across isthmus	17
16a. (15a) Lateral region with red or yellow spots	<i>Etheostoma artesiae</i>
16b. (15a) Lateral region without red or yellow spots.....	<i>Etheostoma radiosum</i>
17a. (15b) Cheek not scaled; infraorbital canal incomplete; lateral body with 8 to 9 vertical bars.....	<i>Etheostoma spectabile</i>
17b. (15b) Cheek scaled; infraorbital canal complete; lateral body with 6 to 8 vertical bars.....	<i>Etheostoma asprigene</i>

FAMILY SCIAENIDAE—drums

Aplodinotus grunniens

FAMILY ELASSOMATIDAE—pygmy sunfishes

Elassoma zonatum

RIO GRANDE AND PECOS RIVER BASINS

KEY TO THE FAMILIES

1a. Body long and slender; without pelvic fins.....	Freshwater Eels – Anguillidae
1b. Body truncated or elongated; with pelvic fins	2
2a. (1b) Caudal fin heterocercal or abbreviated heterocercal	Gars – Lepiososteidae
2b. (1b) Caudal fin homocercal	3
3a. (2b) One dorsal fin; pelvic fins without uniserial spines	4
3b. (2b) One or two dorsal fins; pelvic fins with uniserial spines	13
4a. (3a) With adipose fin.....	5
4b. (3a) Without adipose fin	8
5a. (4a) Without barbels.....	6
5b. (4a) With barbels.....	7
6a. (5a) Scales large, < 50 lateral line scales; incisor teeth present	Tetras – Characidae
6b. (5a) Scales small, > 60 lateral line scales; incisor teeth absent	Trouts – Salmonidae
7a. (5b) Body covered with bony plates; head with one pair of barbels.....	Armored Catfishes – Loricariidae
7b. (5b) Scales absent; head with four to eight barbels	Bullhead Catfishes – Ictaluridae
8a. (4b) Long anal fin with ≥ 17 fin rays	Shads – Clupiedae
8b. (4b) Short anal fin with ≤ 13 rays	9
9a. (8b) Caudal fin forked or emarginated; lateral line usually present.....	10
9b. (8b) Caudal fin truncated or rounded; lateral line usually absent	11

10a. (9a) Inferior, fleshy mouth modified for sucking; > 7 pharyngeal teeth in main row, usually ≥ 10 dorsal fin rays	Suckers – Catostomidae
10b. (9a) Mouth usually not fleshy or modified for sucking; < 7 pharyngeal teeth in main row, usually ≤ 10 dorsal fin rays.....	Carps and Minnows – Cyprinidae
11a. (9b) Mature males with rounded anal fin; males and females with 3rd anal fin ray branched, no gonopodium present	12
11b. (9b) Mature males with pointed anal fin forming a gonopodium; males and females with 3rd anal fin ray unbranched.	Livebearers – Poeciliidae
12a. (11a) Body robust; teeth in single row are incisor-like and tricuspid (three points on a tooth).	Pupfishes – Cyprinodontidae
12b. (11a) Body elongate; conical (cone-shaped) pointed teeth in a single row or several rows.....	Killifishes – Fundulidae
13a. (3b) Pelvic fin position abdominal or sub-thoracic; dorsal fins widely separated.....	14
13b. (3b) Pelvic fin position thoracic; dorsal fins joined or, if separate, closely adjacent to one another.....	15
14a. (13a) Dorsal fin with 4 thick spines; anal fin with 2-3 spines; adipose eyelids present	Mullets – Mugilidae
14b. (13a) Dorsal fin with 4 to 8 thin spines; anal fin with 1 spine; adipose eyelids absent	Silversides – Atherinopsidae
15a. (13b) One nostril (nare) on each side of head; lateral line interrupted	Cichlids – Cichlidae
15b. (13b) Two nostrils (nares) on each side of head; lateral line complete, incomplete, or absent	16
16a. (15b) Dorsal fin with > 23 fin rays; lateral line extends to tip of caudal fin.....	Drums – Sciaenidae
16b. (15b) Dorsal fin with < 23 fin rays; lateral line, if present, does not extend to tip of caudal fin.....	17

- 17a. (16b) Pelvic fins joined into a sucking disk, gill membranes broadly joined to isthmusGobies – Gobiidae
- 17b. (16b) Pelvic fins not joined, gill membranes free or nearly free from isthmus (may be joined to each other across isthmus)18
- 18a. (17b) Anal fin with 1 to 2 spines..... Perches – Percidae
- 18b. (17b) Anal fin with 3 to 8 spines19
- 19a. (18b) Posterior margin of operculum with a sharp spine; spiny and soft dorsal fin separate or only slightly connected; pseudobranchium present and exposed.....
..... Temparate Basses – Moronidae
- 19b. (18b) Posterior margin of operculum without a sharp spine; spiny and soft dorsal fins connected or with deep notch; pseudobranchium covered or absent.....
.....Sunfishes – Centrarchidae

KEY TO THE SPECIES

FAMILY LEPISOSTEIDAE—gars

- 1a. Large teeth in upper jaw in parallel rows on each side*Atractosteus spatula*
1b. Large teeth in upper jaw one row, although another non-parallel row might be present2
- 2a. (1b) Beak long and narrow, least width goes about 12 to 20 times in length; width of beak at nostrils < eye diameter; snout > $\frac{2}{3}$ of head length..... *Lepisosteus osseus*
2b. (1b) Beak short and blunt, least width goes about 5 to 7 times in length; width of beak at nostrils > eye diameter; snout < $\frac{2}{3}$ of head length *Lepisosteus oculatus*

FAMILY ANGUILLIDAE—freshwater eels

Anguilla rostrata

FAMILY CLUPEIDAE—herrings

- 1a. Twenty-nine to 33 anal fin rays; mouth subterminal and below level of middle of eye; black shoulder spot $\geq$ pupil of eye *Dorosoma cepedianum*
1b. Twenty-four to 28 anal fin rays; mouth terminal and at level of eye; black shoulder spot < pupil of eye*Dorosoma petenense*

FAMILY CYPRINIDAE - minnows

- 1a. More than 15 soft rays on dorsal fin; dorsal and anal fins each with a strong serrated spine2
1b. Fewer than 10 soft rays on dorsal fin; dorsal and anal fins without spine.....3
- 2a. (1a) Upper jaw with two pairs of barbels..... *Cyprinus carpio*
2b. (1a) Upper jaw without barbels..... *Carassius auratus*
- 3a. (1b) Anal fin near caudal fin, distance from snout to origin of anal fin is > 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth with prominent parallel grooves*Ctenopharyngodon idella*
3b. (1b) Anal fin not noticeably near caudal fin: distance from snout to origin of anal fin is < 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth without prominent parallel grooves4

4a. (3b) Intestine wound spirally around swim bladder; keratinous ridge on lower jaw.....	5
4b. (3b) Intestine not wound spirally around swim bladder; keratinous ridge of lower jaw hardly evident.....	6
5a. (4a) Intestine wound completely around swim bladder, large scales, 41 to 58 lateral line scales	<i>Campostoma anomalum</i>
5b. (4a) Intestine only partially wound around swim bladder; 58 to 77 lateral line scales; more common in the Presidio to Big Bend Reach of Rio Grande drainage	<i>Campostoma ornatum</i>
6a. (4b) Upper jaw with frenum, dorsal part of premaxillary bones connected to frenum are not protractible	<i>Rhinichthys cataractae</i>
6b. (4b) Upper jaw without frenum, premaxillary bones are protractible	7
7a. (6b) Abdomen behind pelvic fins with a fleshy keel lacking scales; lateral line greatly decurved, distance between anterior lateral line scale and ventral most lateral line scale is > 3 scales in height.....	<i>Notemigonus crysoleucas</i>
7b. (6b) Abdomen behind pelvic fin with scales; lateral line not greatly decurved, lateral line descends < 3 scales ventrally from highest point	8
8a. (7b) With maxillary barbels, might be small and not observable without opening the mouth or with magnification.....	<i>Macrhybopsis aestivalis</i>
8b. (7b) Without maxillary barbels	9
9a. (8b) Small scales, ≥ 50 lateral line scales; current Texas distribution is Little Aguja Creek in the Rio Grande drainage.....	<i>Gila pandora</i>
9b. (8b) Larger scales, < 45 lateral line scales.....	10
10a. (9b) Predorsal scales appear crowded, smaller than scales on lateral body or appear as overlapping scales; black spot in the middle, anterior portion of the dorsal fin.....	11
10b. (9b) Predorsal scales not crowded; without black spot in the middle, anterior portion of the dorsal fin	12
11a. (10a) Caudal spot, if distinct, continuous with mid-lateral stripe; lateral line incomplete; intestine long, more than twice the standard length.....	<i>Pimephales promelas</i>

11b. (10a) Caudal spot distinct from mid-lateral stripe; lateral line complete, intestine forming a short S-shaped loop	<i>Pimephales vigilax</i>
12a. (10b) Long intestine in a flat coil.....	13
12b. (10b) Short S-shaped intestine	16
13a. (12a) Black mid-lateral stripe extends through eye to snout; eye width greater than or equal to snout length.....	14
13b. (12a) Mid-lateral stripe, if present (sometimes appears as a broad, diffuse band of melanophores), does not extend through the eye to the snout; eye width less than snout length	<i>Hybognathus amarus</i>
14a. (13a) Scales outlined with melanophores, most noticeable dorsal of mid-lateral stripe, forming a cross-hatched appearance; more of a triangular shaped caudal spot; sympatric with.....	<i>Dionda diaboli</i>
14b. (13a) Scales equally covered with melanophores; more of a rounded caudal spot ...	15
15a. (14b) Located (all water bodies) downstream from I-10 in the Pecos and within and downstream from Lake Amistad in the Rio Grande	<i>Dionda argentosa</i>
15b. (14b) Complete description pending. Based on genetic analyses, located in Trans Pecos region (all water bodies) upstream from I-10 in the Pecos River and upstream from Lake Amistad in the Rio Grande. Not sympatric with other <i>Dionda</i>	<i>Dionda episcopa</i>
16a. (12b) Moderately decurved lateral line; diamond-shaped scales; dark shoulder patch present; melanophores concentrated between rays of dorsal and anal fins	17
16b. (12b) Lateral line incomplete, complete-straight, or complete-slightly decurved; scales not noticeably diamond-shaped; without dark shoulder patch; melanophores concentrated along rays of dorsal and anal fins	19
17a. (16a) Terminal mouth	<i>Cyprinella lutrensis</i>
17b. (16a) Sub-terminal mouth	18
18a. (17b) A thick distinct black bar extends from lower jaw through isthmus; caudal fin base without a large black spot	<i>Cyprinella proserpina</i>
18b. (17b) Caudal fin base with a large black spot, about size of eye....	<i>Cyprinella venusta</i>

19a. (16b) Dorsal fin origin opposite or anterior to pelvic fin origin	20
19b. (16b) Dorsal fin origin posterior to pelvic fin origin	23
20a. (19a) Lateral line scales markedly elevated (taller than wide) anteriorly, elevated scale height 2 to 5 times scale width.....	<i>Notropis buchanani</i>
20b. (19a) Lateral line scales not markedly elevated anteriorly, scale height 1 to 2 times scale width	21
21a. (20b) Black mid-lateral stripe; melanophores form double dashes above and below the lateral line inferior to mid-lateral stripe between pectoral and pelvic fins	<i>Notropis braytoni</i>
21b. (20b) Faint or absent mid-lateral stripe.....	22
22a. (21b) Melanophores form double dashes above and below the entire lateral line; without scattered, black melanophores on dorsal of body.....	<i>Notropis stramineus</i>
22b. (21b) If present, melanophores form double dashes above and below the anterior portion of the lateral line; with scattered, black melanophores on dorsal of body	<i>Notropis chihuahua</i>
23a. (19b) Sub-terminal mouth	<i>Notropis simus</i>
23b. (19b) Terminal mouth	24
24a. (23b) Depressed pelvic fins reach or extend past origin of anal fin; eye larger, eye diameter greater than snout length.....	<i>Notropis amabilis</i>
24b. (23b) Depressed pelvic fins do not reach origin of anal fin; eye smaller, eye diameter about equal to snout length	<i>Notropis jemezianus</i>

FAMILY CATOSTOMIDAE—suckers

1a. Dorsal fin long, base > than $\frac{1}{3}$ of standard length; 22 to 30 dorsal fin rays	2
1b. Dorsal fin short, base < than $\frac{1}{4}$ of standard length; 4 to 18 dorsal fin rays	5
2a. (1a) Small scales, lateral line scales > 50; eye closer to back of head than to tip of snout; head abruptly more slender than body; papillose lips.....	<i>Cycleptus elongatus</i>
2b. (1a) Large scales, lateral line scales < 45; eye closer to tip of snout than back of head; plicate lips	3

- 3a. (2b) Subopercle triangular, broadest toward base; knob present at tip of lower lip; blunt snout, forming level with eye *Carpiodes carpio*
- 3b. (2b) Subopercle semicircular, broadest towards middle; knob absent at tip of lower lip; rounded snout, forming below level of eye4
- 4a. (3b) Body elongate and slender, greatest body depth goes 2.6 to 3.3 times in standard length, and height of anterior rays in dorsal and anal fins often less than 2/3 head length in individuals >300 mm; small eye, eye diameter goes ≥ 2 times in snout length of individuals <300 mm *Ictiobus niger*
- 4b. (3b) Body deep and narrow, greatest body depth goes 2.2 to 2.8 times in standard length, and height of anterior dorsal and anal fin rays often greater than 2/3 head length in individuals >300 mm; large eye, eye diameter goes ≤ 2 times in snout length of individuals <300 mm *Ictiobus bubalus*
- 5a. (1b) 44 to 46 scales along the lateral line; pectoral fin length equal to head length..... *Moxostoma congestum*
- 5b. (1b) 47 to 50 scales along the lateral line; pectoral fin length < head length
..... *Moxostoma austrinum*

FAMILY CHARACIDAE—characins

Astyanax mexicanus

FAMILY ICTALURIDAE—bullhead catfishes

- 1a. Adipose fin joined to the caudal fin or separated by a shallow notch.... *Noturus gyrinus*
- 1b. Adipose fin free at tip, not joined to caudal fin2
- 2a. (1b) Head dorso-ventrally compressed; mouth terminal to superior . *Pylodictis olivaris*
- 2b. (1b) Head rounded; mouth subterminal3
- 3a. (2b) Caudal fin rounded or shallowly emarginate.....4
- 3b. (2b) Caudal fin deeply forked5
- 4a. (3a) Chin barbels completely or partially black; anal fin rays 17 to 24; anal fin broadly rounded *Ameiurus melas*
- 4b. (3a) Chin barbels white or yellow; anal fin rays 24 to 27; margin of anal fin generally straight..... *Ameiurus natalis*

- 5a. (3b) Anal fin rays 30 to 36; anal fin free margin is straight; medial keel-like ridge anterior to dorsal fin forms humped back appearance *Ictalurus furcatus*
- 5b. (3b) Anal fin rays 22 to 29; anal fin free margin is rounded; no humped back appearance.....6
- 6a. (5b) Anal fin rays 27 to 29; pectoral fin spine goes < 5 times into standard length; random scattering of few black spots may be present *Ictalurus punctatus*
- 6b. (5b) Anal fin rays 22 to 26; pectoral fin spine goes > 5 times into standard length; diffuse black spots on sides..... *Ictalurus lupus*

FAMILY LORICARIIDAE—suckermouth catfishes

- 1a. Dorsal fin short with ≤ 9 rays..... *Hypostomus plecostomus*
- 1b. Dorsal fin long with ≥ 10 rays; dark spots forming extensive vermiculations on sides and ventral surface *Pterygoplichthys disjunctivus*

FAMILY SALMONIDAE—salmons

- 1a. Lateral scale rows 120 to 140; basibranchial teeth absent; paired fins with a white border; no deep red to orange slash on each side of throat along inner side of dentary bone; small spots heavily scattered along sides and caudal fin *Oncorhynchus mykiss*
- 1b. Lateral scale rows 150 to 180; basibranchial teeth usually present, but small or vestigial; paired fins uniformly brown or reddish but without a white border; deep red to orange slash on each side of throat along inner side of dentary bone; large spots concentrated on caudal peduncle in adults..... *Oncorhynchus clarki*

FAMILY MUGILIDAE—mulletts

- 1a. Lower jaw rounded, without a symphyseal knob; lower limb of 1st gill arch with 17 to 20 gill rakers; no adipose eyelid; scales ctenoid *Agonostomus monticola*
- 1b. Lower jaw angular, with a prominent symphyseal knob; lower limb of 1st gill arch with 25 to 60 gill rakers; adipose eyelid well developed in adults; scales cycloid in young, ctenoid in adults *Mugil cephalus*

FAMILY ATHERINOPSIDAE—New World silversides

- 1a. Scales ctenoid, rough to the touch; double pairs of black spots on dorsum; bases of dorsal and anal fin covered with scales.....*Membras martinica*
- 1b. Scales cycloid, smooth to the touch; dorsum with crosshatching, but not double pairs of black spots; bases of dorsal and anal fins not covered with scales; horizontal distance between spinous dorsal and anal fin origin less than 7% of standard length.....
.....*Menidia audens*

FAMILY FUNDULIDAE—topminnows

- 1a. Distance from origin of dorsal fin to end of hypural plate < distance from origin of dorsal fin to preopercle or occasionally about equal to that distance; more than 30 longitudinal scale rows2
- 1b. Distance from origin of dorsal fin to end of hypural plate > distance from origin of dorsal fin to preopercle; 30 or fewer longitudinal scale rows..... *Lucania parva*
- 2a. (1a) More than 40 longitudinal scale rows; dark vertical barring; gill slit not extending dorsal to uppermost pectoral fin ray*Fundulus zebrinus*
- 2b. (1a) Fewer than 40 longitudinal scale rows; gill slit extending dorsal to uppermost pectoral fin ray *Fundulus grandis*

FAMILY CYPRINODONTIDAE—pupfishes

- 1a. Abdomen without scales anterior to pelvic fins..... *Cyprinodon pecosensis*
- 1b. Abdomen with scales anterior to pelvic fins2
- 2a. (1b) Six to 7 anal fin rays3
- 2b. (1b) Greater than 8 anal fin rays4
- 3a. (2a) Dark blotches form a lateral stripe; found in small springs near Balmorhea, TX *Cyprinodon elegans*
- 3b. (2a) Faint blotches deeper than wide; found in Devils River and Alamito Creek *Cyprinodon eximius*
- 4a. (2b) Five to 8 triangular dark bars wide dorsally, coming to a point ventrally*Cyprinodon variegatus*
- 4b. (2b) Lateral blotches wider than deep; found only in Leon Creek. *Cyprinodon bovinus*

FAMILY POECILIIDAE—livebearers

- 1a. Origin of dorsal fin anterior to anal fin origin; intestinal canal long with many convolutions.....2
- 1b. Origin of dorsal fin posterior to anal fin origin; intestinal canal short with few convolutions.....3
- 2a. (1a) Dorsal fin rays 12 to 14; dorsal fin base more than $\frac{1}{2}$ predorsal length; rows of dark spots on scales obscure diamond-shaped color pattern*Poecilia latipinna*
- 2b. (1a) Dorsal fin rays 10 to 12; dorsal fin base $< \frac{1}{2}$ predorsal length; dark spots on scales do not obscure diamond-shaped color pattern; only exists as females.....
.....*Poecilia formosa*
- 3a. (1b) Spines at tip of 3rd anal fin ray of male gonopodium (first enlarged ray) 1 to 3 times longer than wide4
- 3b. (1b) Spines at tip of 3rd anal fin ray of male gonopodium 4 to 10 times longer than wide5
- 4a. (3a) Dorsal fin rays 6 (rarely 7); distal end of the 4th fin ray of gonopodium in male parallel or curved in only a weak arch..... *Gambusia affinis*
- 4b. (3a) Dorsal fin rays 7; distal end of the 4th fin ray of gonopodium in male curved in a wide arch; found in Devil's River..... *Gambusia speciosa*
- 5a. (3b) Dorsal fin rays 9 (rarely 10); predorsal stripe distinct and broad; found in San Felipe Springs *Gambusia krumholzi*
- 5b. (3b) Dorsal fin rays 7 to 8; predorsal stripe thin or absent6
- 6a. (5b) Lateral stripe broad; caudal fin without prominent black markings; markings on sides crescentic; tip of anterior branch of 4th ray of male gonopodium does not extend to tip of posterior branch.....7
- 6b. (5b) Lateral stripe thin and threadlike; caudal fin with prominent black markings; markings on sides rounded specks; tip of anterior branch of 4th ray of male gonopodium extends as far as tip of posterior branch.....8
- 7a. (6a) Elbow of gonopodium composed of usually 4 fused segments; no dark markings around anus of mature females. Likely extirpated.....*Gambusia senilis*
- 7b. (6a) Elbow of gonopodium composed of usually 2 (rarely 3) fused segments; dark markings on anus of mature females *Gambusia gaigei*

- 8a. (7b) Postanal streak prominent (darker than markings on scale pockets); black markings on mouth; median row of spots on caudal fin; median row of spots on dorsal fin; terminal hook on 4th and 5th rays of gonopodium angular at tip *Gambusia geiseri*
- 8b. (7b) Postanal streak weaker than markings on scale pockets; dusky or no markings on mouth; no prominent spots in middle of caudal fin; a subbasal row of spots on dorsal fin; terminal hooks on 4th and 5th rays of gonopodium rounded at tip *Gambusia nobilis*

FAMILY MORONIDAE—temperate basses

- 1a. Body depth goes < 3 times in standard length; teeth in single patch on back of tongue.....*Morone chrysops*
- 1b. Body depth goes > 3 times in standard length; teeth in 2 parallel patches on back of tongue.....*Morone saxatilis*

FAMILY CENTRARCHIDAE—sunfishes

- 1a. Five to 8 anal spines2
- 1b. Three anal spines.....3
- 2a. (1a) Dorsal fin set back on body, length of dorsal fin base < distance from its origin to posterior margin of eye; lateral body with wide to narrow dorsal black bands; ≤ 6 dorsal spines..... *Pomoxis annularis*
- 2b. (1a) Dorsal fin set forward on body, length of dorsal fin base equal to or greater than distance from its origin to posterior margin of eye; lateral body with checkerboard black and light pattern; ≥7 dorsal spines*Pomoxis nigromaculatus*
- 3a. (1b) Body slender, body depth contained > 3 times into standard length.....4
- 3b. (1b) Body deep, body depth contained < 3 times into standard length.....5
- 4a. (3a) Dorsal fins narrowly joined at base forming a deep notch; upper jaw extends past posterior margin of eye in adults; mid-lateral stripe generally complete, rows of spots ventral to mid-lateral stripe faint and incomplete*Micropterus salmoides*
- 4b. (3a) Dorsal fins broadly joined at base forming a shallow notch; upper jaw does not reach past posterior portion of eye; bases of soft dorsal and anal fins scaled
.....*Micropterus dolomieu*

5a. (3b) Teeth on tongue; head and opercle with 3 to 5 distinct dark and light longitudinal stripes; red spot on posterior margin of opercle flap in fresh specimens....	<i>Lepomis gulosus</i>
5b. (3b) No teeth on tongue; head and opercle lacking distinct dark and light longitudinal stripes	6
6a. (5b) Pectoral fins long and pointed, reach anterior portion of eye or beyond when bent forward.....	7
6b. (5b) Pectoral fins short and rounded, do not reach past eye when bent forward	8
7a. (6a) Opercle flap stiff to its margin, posterior margin either red or orange in live specimens	<i>Lepomis microlophus</i>
7b. (6a) Opercle flap flexible, posterior margin not red or orange in live specimens	<i>Lepomis macrochirus</i>
8a. (6b) Black opercle flap stiff near the posterior margin with bone supporting all or majority of the flap.....	9
8b. (6b) Black opercle flap flexible near the posterior margin without bone supporting majority of the flap.....	10
9a. (8a) Body elongated with black spot on posterior base of soft dorsal fin	<i>Lepomis cyanellus</i>
9b. (8a) Body rounded without black spot on posterior base of soft dorsal fin; lateral body with alternating stripes formed from black and red spots	<i>Lepomis miniatus</i>
10a. (8b) Opercle flap black to the posterior margin; opercle flap is thin near the opercle bone with the narrowest width of the flexible portion of the flap about the same diameter of the eye pupil.....	<i>Lepomis auritus</i>
10b. (8b) Opercle flap black and surrounded by white on the posterior margin; opercle flap is wide with narrowest width of the flexible flap is about two times the diameter of the eye pupil.....	<i>Lepomis megalotis</i>

FAMILY PERCIDAE—perches

1a. Upper jaw extending to below the middle of the eye or farther; preopercle strongly serrate; caudal fin forked	<i>Sander vitreus</i>
1b. Upper jaw not extending to beneath middle of eye; preopercle smooth or weakly serrated	2

- 2a. (1b) Snout conical, extends beyond upper lip; body with thin vertical bars; caudal fin straight, rounded, or slightly emarginate *Percina macrolepid*
 2b. (1b) Snout less conical, does not extend beyond upper lip 2
- 3a. (2b) Lateral line arched upward *Etheostoma gracile*
 3b. (2b) Lateral line straight..... *Etheostoma grahami*

FAMILY SCIAENIDAE—drums

Aplodinotus grunniens

FAMILY CICHLIDAE—cichlids

- 1a. Anal fin spines 5 to 6 *Herichthys cyanoguttatus*
 1b. Anal fin spines < 5 (usually 3)..... 2
- 2a. (1b) Gill rakers 14 to 20 (usually 17 to 18) on lower part of first gill arch; most teeth in outer row are unicuspid in adults; sides with 3 or 4 dark blotches or with no markings; no yellow on dorsal fin; caudal fin without distinct vertical stripes
 *Oreochromis mossambicus*
- 2b. (1b) Gill rakers 18 to 26 on lower part of 1st gill arch; outer row of teeth bicuspid in adults; caudal fin unmarked, or with vague, irregular dark markings, caudal fin often with a broad, red distal margin; young often with vertical bands on caudal fin
 *Oreochromis aureus*

FAMILY GOBIIDAE—gobies

- 1a. Body without scales *Gobiosoma bosc*
 1b. Body mostly scaled; Scales small, > 70 rows in lateral series..... *Awaous banana*

SABINE AND NECHES RIVER BASINS

KEY TO THE FAMILIES

- 1a. Jawless, disc-shaped mouth; without pectoral and pelvic fins; 7 pairs of external gill openings Lampreys – Petromyzontidae
- 1b. Jawed mouth; one gill opening on each side of head; with pectoral, pelvic, or both fins.....2

- 2a. (1b) Both eyes on one side of head; without right pectoral fin American Soles – Achiridae
- 2b. (1b) One eye on either side of head; with both pectoral fins3

- 3a. (2b) Body long and slender; without pelvic fins..... Freshwater Eels – Anguillidae
- 3b. (2b) Body truncated or elongated; with pelvic fin 4

- 4a. (3b) Caudal fin heterocercal or abbreviated heterocercal5
- 4b. (3b) Caudal fin homocercal7

- 5a. (4a) Caudal fin heterocercal, body appears scaleless, except for a few ganoid scales at the base of caudal fin; long, paddle shaped snout.....Paddlefish – Polyodontidae
- 5b. (4a) Caudal fin abbreviated heterocercal; body with ganoid or cycloid scales6

- 6a. (5b) Body covered with ganoid scales; snout formed into a beak; without gular plate..... Gars – Lepisosteidae
- 6b. (5b) Body covered with cycloid scales, snout not formed into a beak, with a gular plate.....Bowfin – Amiidae

- 7a. (4b) Jaws duckbilled Pickerels – Esocidae
- 7b. (4b) Jaws not duckbilled8

- 8a. (7b) One dorsal fin; pelvic fins without uniserial spines9
- 8b. (7b) One or two dorsal fins; pelvic fins with uniserial spines15

9a. (8a) With adipose fin.....	10
9b. (8a) Without adipose fin	11
10a. (9a) Without barbels.....	Trouts – Salmonidae
10b. (9a) With barbels.....	Bullhead Catfishes – Ictaluridae
11a. (9b) Long anal fin with ≥ 17 fin rays	Shads – Clupiedae
11b. (9b) Short anal fin with ≤ 13 rays	12
12a. (11b) Caudal fin forked or emarginated; lateral line usually present.....	13
12b. (11b) Caudal fin truncated or rounded; lateral line usually absent	14
13a. (12a) Inferior, fleshy mouth modified for sucking; > 7 pharyngeal teeth in main row, usually ≥ 10 dorsal fin rays	Suckers – Catostomidae
13b. (12a) Mouth usually not fleshy or modified for sucking; < 7 pharyngeal teeth in main row, usually ≤ 10 dorsal fin rays.....	Minnows – Cyprinidae
14a. (12b) Mature males with rounded anal fin; males and females with 3rd anal fin ray branched, no gonopodium present	Killifishes – Fundulidae
14b. (12b) Mature males with pointed anal fin forming a gonopodium; males and females with 3rd anal fin ray unbranched.	Livebearers – Poeciliidae
15a. (8b) Anus anterior to pelvic fins; > 5 soft rays on each pelvic fin.....	Pirate Perch – Aphredoderidae
15b. (8b) Anus posterior to pelvic fins; 5 soft rays on pelvic fins.....	16
16a. (15b) Pelvic fin position abdominal or sub-thoracic; dorsal fins widely separated...	17
16b. (15b) Pelvic fin position thoracic; dorsal fins joined or, if separate, closely adjacent to one another.....	18
17a. (16a) Dorsal fin with 4 thick spines; anal fin with 2-3 spines; adipose eyelids present	Mullets – Mugilidae
17b. (16a) Dorsal fin with 4 to 8 thin spines; anal fin with 1 spine; adipose eyelids absent	Silversides – Atherinopsidae

18a. (16b) One nostril (nare) on each side of head; lateral line interrupted	
.....Cichlids – Cichlidae	
18b. (16b) Two nostrils (nares) on each side of head; lateral line complete, incomplete, or absent	19
19a. (17b) Dorsal fin with > 23 fin rays; lateral line extends to tip of caudal fin.....	
..... Drums – Sciaenidae	
19b. (17b) Dorsal fin with < 23 fin rays; lateral line, if present, does not extend to tip of caudal fin.....	20
20a. (19b) Anal fin with 1 to 2 spines.....	Perches – Percidae
20b. (19b) Anal fin with 3 to 8 spines	21
21a. (20b) Posterior margin of operculum with a sharp spine; spiny and soft dorsal fin separate or only slightly connected; pseudobranchium present and exposed.....	
..... Temperate Basses – Moronidae	
21b. (20b) Posterior margin of operculum without a sharp spine; spiny and soft dorsal fins connected or with deep notch; pseudobranchium covered or absent.....	22
22a. (21b) Lateral line present or incomplete	Sunfishes – Centrarchidae
22b. (21b) Lateral line absent	Pygmy Sunfishes – Elasmobranchidae

KEY TO THE SPECIES

FAMILY PETROMYZONTIDAE – lampreys

- 1a. Disc-shaped mouth large, diameter of mouth $>$ body width and about 140 times into total length; with rasping teeth; adults with well-developed intestine.....
.....*Ichthyomyzon castaneus*
- 1b. Disc-shaped mouth small, diameter of mouth $\leq$ than body width and about 170 to 250 times into total length; without rasping teeth; adults without well-developed intestine
.....*Ichthyomyzon gagei*

FAMILY POLYODONTIDAE—paddlefishes

Polyodon spathula

FAMILY LEPISOSTEIDAE—gars

- 1a. Large teeth in upper jaw in parallel rows on each side*Atractosteus spatula*
- 1b. Large teeth in upper jaw one row, although another non-parallel row might be present2
- 2a. (1b) Beak long and narrow, least width goes about 12 to 20 times in length; width of beak at nostrils $<$ eye diameter; snout $>$ $\frac{2}{3}$ of head length..... *Lepisosteus osseus*
- 2b. (1b) Beak short and blunt, least width goes about 5 to 7 times in length; width of beak at nostrils $>$ eye diameter; snout $<$ $\frac{2}{3}$ of head length *Lepisosteus oculatus*

FAMILY AMIIDAE—bowfins

Amia calva

FAMILY ANGUILLIDAE—freshwater eels

Anguilla rostrata

FAMILY CLUPEIDAE—herrings

- 1a. Twenty-nine to 33 anal fin rays; mouth subterminal and below level of middle of eye; black shoulder spot $\geq$ pupil of eye *Dorosoma cepedianum*
- 1b. Twenty-four to 28 anal fin rays; mouth terminal and at level of eye; black shoulder spot $<$ pupil of eye*Dorosoma petenense*

FAMILY CYPRINIDAE - minnows

1a. More than 15 soft rays on dorsal fin; dorsal and anal fins each with a strong serrated spine	2
1b. Fewer than 10 soft rays on dorsal fin; dorsal and anal fins without spine.....	3
2a. (1a) Upper jaw with two pairs of barbels.....	<i>Cyprinus carpio</i>
2b. (1a) Upper jaw without barbels.....	<i>Carassius auratus</i>
3a. (1b) fin near caudal fin, distance from snout to origin of anal fin is > 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth with prominent parallel grooves	<i>Ctenopharyngodon idella</i>
3b. (1b) Anal fin not noticeably near caudal fin: distance from snout to origin of anal fin is < 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth without prominent parallel grooves	4
4a. (3b) Abdomen behind pelvic fins with a fleshy keel lacking scales; lateral line greatly decurved, distance between anterior lateral line scale and ventral most lateral line scale is > 3 scales in height.....	<i>Notemigonus crysoleucas</i>
4b. (3b) Abdomen behind pelvic fin with scales; lateral line not greatly decurved, lateral line descends < 3 scales ventrally from highest point	5
5a. (4b) With maxillary barbels, might be small and not observable without opening the mouth or with magnification.....	6
5b. (4b) Without maxillary barbels.....	7
6a. (5a) Mouth terminal; distinct black spot located anteriorly on dorsal fin; pharyngeal teeth on main row 5-4 or 5-5.....	<i>Semotilus atromaculatus</i>
6b. (5a) Mouth subterminal or inferior; no distinct black spot on dorsal fin; pharyngeal teeth on main row 4-4	<i>Macrhybopsis hyostoma</i>
7a. (5b) Thick lower lip at corners, mouth noticeably ventral; black spot at base of caudal fin	<i>Phenacobius mirabilis</i>
7b. (5b) Lower lip thin or not noticeably thick; with or without black spot at base of caudal fin.....	8

8a. (7b) Predorsal scales appear crowded, smaller than scales on lateral body or appear as overlapping scales; black spot in the middle, anterior portion of the dorsal fin	9
8b. (7b) Predorsal scales not crowded; without black spot in the middle, anterior portion of the dorsal fin	10
9a. (8a) Caudal spot, if distinct, continuous with mid-lateral stripe; lateral line incomplete; intestine long, more than twice the standard length.....	<i>Pimephales promelas</i>
9b. (8a) Caudal spot distinct from mid-lateral stripe; lateral line complete, intestine forming a short S-shaped loop	<i>Pimephales vigilax</i>
10a. (8b) Long intestine in a flat coil	11
10b. (8b) Short S-shaped intestine	12
11a. (10a) Terminal mouth; scales are diamond-shaped, most noticeable dorsally; Sabine drainage.....	<i>Hybognathus hayi</i>
11b. (10a) Sub-terminal mouth; scales not diamond-shaped.....	<i>Hybognathus nuchalis</i>
12a. (10b) Moderately decurved lateral line; diamond-shaped scales; dark shoulder patch present; melanophores concentrated between rays of dorsal and anal fins	13
12b. (10b) Lateral line incomplete, complete-straight, or complete-slightly decurved; scales not noticeably diamond-shaped; without dark shoulder patch; melanophores concentrated along rays of dorsal and anal fins	14
13a. (12a) Sub-terminal mouth; caudal fin base with a caudal spot larger than eye; no shoulder patch	<i>Cyprinella venusta</i>
13b. (12a) Terminal mouth; no caudal spot	<i>Cyprinella lutrensis</i>
14a. (12b) Distinct and separate black dash at base of dorsal fin; apparent when viewed from above; pharyngeal teeth count usually 0,4-4,0	15
14b. (12b) No distinct and separate black dash at base of dorsal fin; pharyngeal teeth count usually 1,4-4,1 or 2,4-4,2	17
15a. (14a) Lateral line scales markedly elevated (taller than wide) anteriorly, elevated scale height 2 to 5 times scale width.....	16
15b. (14a) Lateral line scales not markedly elevated anteriorly, scale height 1 to 2 times scale width	<i>Notropis sabinae</i>

- 16a. (15a) Dorsal and lateral body with melanophores outlining scales; with pronounced black lateral stripe; dorsal fin height goes 2.1 or more times in pre-dorsal length; infraorbital canal complete *Notropis volucellus*
- 16b. (15a) Dorsal and lateral body with sparse melanophores; scales outlined with melanophores are rare; pre-dorsal black spot is prominent and distinct from mid-dorsal stripe; dorsal fin height goes 2.0 or fewer times in pre-dorsal length; infraorbital canal incomplete *Notropis buchanani*
- 17a. (14b) Depressed dorsal fin longer than head *Hybopsis amnis*
- 17b. (14b) Depressed dorsal fin shorter than head 19
- 18a. (17b) Mouth is sub-terminal; pharyngeal teeth are 0,4-4,0 *Notropis atrocaudalis*
- 18b. (17b) Mouth is terminal; pharyngeal teeth are 1,4-4,1 or 2,4-4,2 or 5-5 19
- 19a. (18b) Dorsal fin origin opposite or anterior to pelvic fin origin 20
- 19b. (18b) Dorsal fin origin posterior to pelvic fin origin 23
- 20a. (19a) Prominent mid-lateral stripe, extending through eye 21
- 20b. (19a) No prominent mid-lateral stripe present *Notropis shumardi*
- 21a. (20a) Pharyngeal teeth 5-5; mouth small and almost vertical *Opsopoeodus emiliae*
- 21b. (20a) Pharyngeal teeth are 1,4-4,1 or 2,4-4,2; mouth large and oblique 22
- 22a. (21b) Usually 8 anal fin rays; inside of mouth with black melanophores; dorsal fin insertion is opposite to pelvic fin insertion *Notropis chalybaeus*
- 22b. (21b) Usually 7 anal fin rays; inside of mouth without black melanophores; dorsal fin insertion is anterior to pelvic fin insertion *Notropis texanus*
- 23a. (19b) Small scales, ≥ 41 lateral line scales, > 25 predorsal scales
..... *Notropis atherinoides*
- 23b. (19b) Moderate-sized scales, ≤ 40 lateral line scales, < 24 predorsal scales 24

- 24a. (23b) Dorsal fin with black melanophores extending from mid-dorsal stripe into the anterior fin ray; edges of the anterior dorsolateral scales are outlined with black melanophores, producing chevron pattern. *Lythrurus umbratilis*
- 24b. (23b) Dorsal fin with black melanophores not extending from mid-dorsal stripe into the anterior fin ray, lacks chevron pattern *Lythrurus fumeus*

FAMILY CATOSTOMIDAE—suckers

- 1a. Dorsal fin long, base > than $\frac{1}{3}$ of standard length; 22 to 30 dorsal fin rays2
- 1b. Dorsal fin short, base < than $\frac{1}{4}$ of standard length; 4 to 18 dorsal fin rays6
- 2a. (1a) Small scales, lateral line scales > 50; eye closer to back of head than to tip of snout; head abruptly more slender than body; papillose lips *Cycleptus elongatus*
- 2b. (1a) Large scales, lateral line scales < 45; eye closer to tip of snout than back of head; plicate lips3
- 3a. (2b) Subopercle triangular, broadest toward base; knob present at tip of lower lip; blunt snout, forming level with eye *Carpiodes carpio*
- 3b. (2b) Subopercle semicircular, broadest towards middle; knob absent at tip of lower lip; rounded snout, forming below level of eye4
- 4a. (3b) Mouth large and oblique; upper jaw length is equal to snout length.....
..... *Ictiobus cyprinellus*
- 4b. (3b) Mouth small and nearly horizontal; upper jaw shorter than snout5
- 5a. (4b) Body elongate and slender, greatest body depth goes 2.6 to 3.3 times in standard length, and height of anterior rays in dorsal and anal fins often less than $\frac{2}{3}$ head length in individuals >300 mm; small eye, eye diameter goes ≥ 2 times in snout length of individuals <300 mm *Ictiobus niger*
- 5b. (4b) Body deep and narrow, greatest body depth goes 2.2 to 2.8 times in standard length, and height of anterior dorsal and anal fin rays often greater than $\frac{2}{3}$ head length in individuals >300 mm; large eye, eye diameter goes ≤ 2 times in snout length of individuals <300 mm *Ictiobus bubalus*
- 6a. (1b) Lateral line complete and well developed; air bladder with 3 chambers *Moxostoma poecilurum*
- 6b. (1b) Lateral line incomplete or absent; air bladder with 2 chambers7

- 7a. (6b) Lateral line incomplete; rows of spots.....*Minytrema melanops*
 7b. (6b) Lateral line absent8

- 8a. (7b) Scales larger, lateral scale count 34 to 37; eye larger, eye length $\frac{1}{2}$ of snout length; dorsal fin rays 11 or 12; back with crescentic scale marks.....*Erimyzon sucetta*
 8b. (7b) Scales smaller, lateral scale count 39 to 43; eye smaller, eye length $< \frac{1}{2}$ of snout length; dorsal fin rays 9 or 10; back without crescentic scale marks *Erimyzon claviformis*

FAMILY ICTALURIDAE—bullhead catfishes

- 1a. Adipose fin joined to the caudal fin or separated by a shallow notch.....2
 1b. Adipose fin free at tip, not joined to caudal fin3

- 2a. (1a) Mouth terminal; pectoral fin spine not serrated; lower lip and chin not heavily speckled with black pigment.....*Noturus gyrinus*
 2b. (1a) Mouth sub-terminal; pectoral spine serrated; lower lip and chin heavily speckled with black pigment.....*Noturus nocturnus*

- 3a. (1b) Head dorso-ventrally compressed; mouth terminal to superior . *Pylodictis olivaris*
 3b. (1b) Head rounded; mouth subterminal4

- 4a. (3b) Caudal fin rounded or shallowly emarginate.....5
 4b. (3b) Caudal fin deeply forked6

- 5a. (4a) Chin barbels completely or partially black; anal fin rays 17 to 24; anal fin broadly rounded*Ameiurus melas*
 5b. (4a) Chin barbels white or yellow; anal fin rays 24 to 27; margin of anal fin generally straight
 *Ameiurus natalis*

- 6a. (4b) Anal fin rays 30 to 36; anal fin free margin is straight; medial keel-like ridge anterior to dorsal fin forms humped back appearance*Ictalurus furcatus*
 6b. (4b) Anal fin rays 22 to 29; anal fin free margin is rounded; no humped back appearance.....*Ictalurus punctatus*

FAMILY SALMONIDAE—salmons

Oncorhynchus mykiss

FAMILY ESOCIDAE—pikes and pickerels

1a. Snout short, distance from tip of snout to center of eye $\leq$ distance from center of eye to rear margin of operculum; < 115 scale rows along body *Esox americanus*

1b. Snout long, distance from tip of snout to center of eye > distance from center of eye to rear margin of operculum; > 120 scale rows along body *Esox niger*

FAMILY APHREDODERIDAE—pirate perch

Aphredoderus sayanus

FAMILY MUGILIDAE—mulletts

1a. Lower jaw rounded, without a symphyseal knob; lower limb of 1st gill arch with 17 to 20 gill rakers; no adipose eyelid; scales ctenoid *Agonostomus monticola*

1b. Lower jaw angular, with a prominent symphyseal knob; lower limb of 1st gill arch with 25 to 60 gill rakers; adipose eyelid well developed in adults; scales cycloid in young, ctenoid in adults *Mugil cephalus*

FAMILY ATHERINOPSIDAE—New World silversides

1a. Scales small, > 60 scales in lateral series, jaws produced into a short beak; snout length > eye length; > 20 anal fin rays *Labidesthes sicculus*

1b. Scales large, < 50 scales in lateral series; jaws not produced into a beak; snout length $\leq$ eye length; < 20 anal fin rays *Menidia audens*

FAMILY FUNDULIDAE—topminnows

1a. Body with a distinct black lateral band 2

1b. Body without a distinct black lateral band 3

2a. (1a) Distinct black spots on anterior dorso-lateral region are as pronounced as lateral stripe; distinct black spots throughout dorsal and caudal fins *Fundulus olivaceus*

2b. (1a) Faint black spots on anterior dorso-lateral region are not as pronounced as lateral stripe; distinct black spots near base of dorsal and caudal fins *Fundulus notatus*

- 3a. (1b) Red to dark spots in multiple rows longitudinally along lateral sides; usually with dark subocular bar*Fundulus blairae*
- 3b. (1b) Body mottled, barred or irregularly spotted; no dark subocular bar
.....*Fundulus chrysotus*

FAMILY POECILIIDAE—livebearers

- 1a. Origin of dorsal fin anterior to anal fin origin; intestinal canal long with many convolutions*Poecilia latipinna*
- 1b. Origin of dorsal fin posterior to anal fin origin; intestinal canal short with few convolutions2
- 2a. (1b) Dorsal fin origin slightly behind anal fin origin; dark band on sides with vertical bars; large black spots near bases of dorsal and caudal fins of both sexes and on anal fin of females*Heterandria formosa*
- 2b. (1b) Dorsal fin origin well behind anal fin origin; no dark band on sides; median fins without large black spots near their bases *Gambusia affinis*

FAMILY MORONIDAE—temperate basses

- 1a. Dorsal fins united at base; 2nd and 3rd anal fin spines approximately equal in length; no teeth on tongue; 9 to 10 anal fin soft rays; stripes along sides usually sharply broken and offset above front of anal fin *Morone mississippiensis*
- 1b. Dorsal fins separated; 2nd anal fin spine much shorter than 3rd; base of tongue with teeth; 11 to 13 anal fin soft rays; stripes along sides usually continuous2
- 2a. (1b) Body depth goes < 3 times in standard length; teeth in single patch on back of tongue*Morone chrysops*
- 2b. (1b) Body depth goes > 3 times in standard length; teeth in 2 parallel patches on back of tongue*Morone saxatilis*

FAMILY CENTRARCHIDAE—sunfishes

- 1a. Five to 8 anal spines2
- 1b. Three anal spines4

2a. (1a) Eleven to 13 dorsal fin spines	<i>Centrarchus macropterus</i>
2b. (1a) Six to 8 dorsal fin spines	3
3a. (2b) Dorsal fin set back on body, length of dorsal fin base < distance from its origin to posterior margin of eye; lateral body with wide to narrow dorsal black bands; ≤ 6 dorsal spines.....	<i>Pomoxis annularis</i>
3b. (2b) Dorsal fin set forward on body, length of dorsal fin base equal to or greater than distance from its origin to posterior margin of eye; lateral body with checkerboard black and light pattern; ≥7 dorsal spines	<i>Pomoxis nigromaculatus</i>
4a. (1b) Body slender, body depth contained > 3 times into standard length.....	5
4b. (1b) Body deep, body depth contained < 3 times into standard length.....	6
5a. (4a) Dorsal fins narrowly joined at base forming a deep notch; upper jaw extends past posterior margin of eye in adults; mid-lateral stripe generally complete, rows of spots ventral to mid-lateral stripe faint and incomplete	<i>Micropterus salmoides</i>
5b. (4a) Dorsal fins broadly joined at base forming a shallow notch; upper jaw does not reach past posterior portion of eye; bases of soft dorsal and anal fins scaled	<i>Micropterus punctulatus</i>
6a. (4b) Teeth on tongue; head and opercle with 3 to 5 distinct dark and light longitudinal stripes; red spot on posterior margin of opercle flap in fresh specimens....	<i>Lepomis gulosus</i>
6b. (4b) No teeth on tongue; head and opercle lacking distinct dark and light longitudinal stripes	7
7a. (6b) Pectoral fins long and pointed, reach anterior portion of eye or beyond when bent forward.....	8
7b. (6b) Pectoral fins short and rounded, do not reach past eye when bent forward	10
8a. (7a) Opercle flap stiff to its margin, posterior margin either red or orange in live specimens	<i>Lepomis microlophus</i>
8b. (7a) Opercle flap flexible, posterior margin not red or orange in live specimens	9

- 9a. (8b) Opercle flap black to the margin; black spot on posterior base of soft dorsal fin *Lepomis macrochirus*
- 9b. (8b) Opercle flap outlined with thick white band; lacking black spot on posterior base of soft dorsal fin *Lepomis humilis*
- 10a. (7b) Black opercle flap stiff near the posterior margin with bone supporting all or majority of the flap 11
- 10b. (7b) Black opercle flap flexible near the posterior margin without bone supporting majority of the flap 13
- 11a. (10a) Lateral line incomplete; smaller individuals with black spot surrounded by white margin on posterior base of soft dorsal fin *Lepomis symmetricus*
- 11b. (10a) Lateral line complete; black spot, if present, on posterior base of soft dorsal fin without white margin 12
- 12a. (11b) Body elongated with black spot on posterior base of soft dorsal fin
..... *Lepomis cyanellus*
- 12b. (11b) Body rounded without black spot on posterior base of soft dorsal fin; lateral body with alternating stripes formed from black and red spots *Lepomis miniatus*
- 13a. (10b) Opercle flap black to the posterior margin; opercle flap is thin near the opercle bone with the narrowest width of the flexible portion of the flap about the same diameter of the eye pupil *Lepomis auritus*
- 13b. (10b) Opercle flap black and surrounded by white on the posterior margin; opercle flap is wide with narrowest width of the flexible flap is about two times the diameter of the eye pupil 14
- 14a. (13b) Twelve pectoral fin rays, 3 to 5 cheek scales; opercle flap often with white pigment form speckles, distinct red spots (white in preserved specimens) along lateral line *Lepomis marginatus*
- 14b. (13b) Thirteen to 15 pectoral fin rays, 5 to 7 cheek scales; opercle flaps with red or white margin; 13 to 15 pectoral fin rays *Lepomis megalotis*

FAMILY PERCIDAE—perches

- 1a. Body depth contained in standard length > 7 times 2
- 1b. Body depth contained in standard length < 7 times 3

2a. (1a) Lateral blotches longer than deep	<i>Ammocrypta clara</i>
2b. (1a) Lateral blotches deeper than long.....	<i>Ammocrypta vivax</i>
3a. (1b) Snout conical, extends beyond upper lip; body with ≥ 14 black vertical bars.....	<i>Percina macrolepida</i>
3b. (1b) Snout less conical, does not extend beyond upper lip; body with < 14 black vertical bars or with a pattern other than vertical bars.....	4
4a. (3b) Sides of body with large black blotches; midline of abdomen naked or with enlarged scales	5
4b. (3b) Sides of body without large black blotches; scales on abdomen normal	7
5a. (4a) Upper lip connected to snout by a narrow frenum; blotches on sides of body are rectangle-shaped and bleed downward	<i>Percina shumardi</i>
5b. (4a) Upper lip connected to snout by a broad frenum; blotches on sides of body do not bleed downward	6
6a. (5b) Nape unscaled; blotches on sides of body are rectangle shaped and might appear connected	<i>Percina maculata</i>
6b. (5b) Nape scaled; blotches on sides of body not rectangle shaped	<i>Percina sciera</i>
7a. (4b) Lateral line short, < 6 pored scales; single row of horizontal dashes present	<i>Etheostoma proeliare</i>
7b. (4b) Lateral line long (complete or incomplete), > 6 pored scales; if horizontal dashes present, accompanied by vertical bars	8
8a. (7b) Pectoral fin long; pectoral fin folded forward extends past head	<i>Etheostoma histrio</i>
8b. (7b) Pectoral fin short, pectoral fin folded forward does not extend past head	9
9a. (8b) Lateral line arched upward	10
9b. (8b) Lateral line straight.....	11

- 10a. (9a) Breast without scales; breast and abdomen without black speckles.....
.....*Etheostoma gracile*
- 10b. (9a) Breast with scales; breast and abdomen with black speckles.....
.....*Etheostoma fusiforme*
- 11a. (9b) Lateral body with distinct series of M-shaped pigments; snout rounded and blunt*Etheostoma chlorosoma*
- 11b. (9b) Lateral body without distinct series of M-shaped pigments; snout not noticeably rounded and blunt12
- 12a. (11b) Lateral region with mottling bisected by a light colored lateral stripe..... *Etheostoma parvipinne*
- 12b. (11b) Lateral region without mottling bisected by a light colored lateral stripe13
- 13a. (12b) Gill membranes widely joined across isthmus; lateral region with red or yellow spots*Etheostoma artesiae*
- 13b. (12b) Gill membranes either not joined or barely joined across isthmus; lateral region without spots and with a series of vertical bars located posteriorly
.....*Etheostoma asprigene*

FAMILY SCIAENIDAE—drums

Aplodinotus grunniens

FAMILY ELASSOMATIDAE—pygmy sunfishes

Elassoma zonatum

FAMILY ACHIRIDAE—American soles

Trinectes maculatus

TRINITY AND SAN JACINTO RIVER BASINS

KEY TO THE FAMILIES

- 1a. Jawless, disc-shaped mouth; without pectoral and pelvic fins; 7 pairs of external gill openings Lampreys – Petromyzontidae
- 1b. Jawed mouth; one gill opening on each side of head; with pectoral, pelvic, or both fins.....2

- 2a. (1b) Both eyes on one side of head; without right pectoral fin American Soles – Achiridae
- 2b. (1b) One eye on either side of head; with both pectoral fins3

- 3a. (2b) Body long and slender; without pelvic fins..... Freshwater Eels – Anguillidae
- 3b. (2b) Body truncated or elongated; with pelvic fins 4

- 4a. (3b) Caudal fin heterocercal or abbreviated heterocercal5
- 4b. (3b) Caudal fin homocercal7

- 5a. (4a) Caudal fin heterocercal, body appears scaleless, except for a few ganoid scales at the base of caudal fin; long, paddle shaped snout.....Paddlefish – Polyodontidae
- 5b. (4a) Caudal fin abbreviated heterocercal; body with ganoid or cycloid scales6

- 6a. (5b) Body covered with ganoid scales; snout formed into a beak; without gular plate..... Gars – Lepisosteidae
- 6b. (5b) Body covered with cycloid scales, snout not formed into a beak, with a gular plate.....Bowfin – Amiidae

- 7a. (4b) Jaws duckbilled Pickerels – Esocidae
- 7b. (4b) Jaws not duckbilled8

- 8a. (7b) One dorsal fin; pelvic fins without uniserial spines9
- 8b. (7b) One or two dorsal fins; pelvic fin with a hard spine18

9a. (8a) With adipose fin.....	10
9b. (8a) Without adipose fin	13
10a. (9a) Without barbels.....	12
10b. (9a) With barbels.....	11
11a. (10b) Body covered with bony plates; head with one pair of barbels.....	
.....Armored Catfishes – Loricariidae	
11b. (10b) Scales absent; head with four to eight barbels . Bullhead Catfishes – Ictaluridae	
12a. (10a) Scales large, < 50 lateral line scales; incisor teeth present ...Tetras – Characidae	
12b. (10a) Scales small, > 60 lateral line scales; incisor teeth absent . Trouts – Salmonidae	
13a. (10b) Long anal fin with ≥ 17 fin rays	Shads – Clupiedae
13b. (10b) Short anal fin with ≤ 13 rays	14
14a. (12b) Caudal fin forked or emarginated; lateral line usually present.....	15
14b. (12b) Caudal fin truncated or rounded; without a distinct lateral line in most	16
15a. (14a) Inferior, fleshy mouth modified for sucking; > 7 pharyngeal teeth in main row, usually ≥ 10 dorsal fin rays	Suckers – Catostomidae
15b. (14a) Mouth usually not fleshy or modified for sucking; < 7 pharyngeal teeth in main row, usually ≤ 10 dorsal fin rays.....	Minnows – Cyprinidae
16a. (14b) Mature males with rounded anal fin; males and females with 3rd anal fin ray branched, no gonopodium present	17
16b. (14b) Mature males with pointed anal fin forming a gonopodium; males and females with 3rd anal fin ray unbranched.	Livebearers – Poeciliidae
17a. (16a) Body robust; teeth in single row are incisor-like and tricuspid (three points on a tooth).	Pupfishes – Cyprinodontidae
17b. (16a) Body elongate; conical (cone-shaped) pointed teeth in a single row or several rows.....	Killifishes – Fundulidae

18a. (8b) Anus anterior to pelvic fins; > 5 soft rays on each pelvic fin.....	
.....	Pirate Perch – Aphredoderidae
18b. (8b) Anus posterior to pelvic fins; 5 soft rays on pelvic fins.....	19
19a. (18b) Pelvic fin position abdominal or sub-thoracic; dorsal fins widely separated...	20
19b. (18b) Pelvic fin position thoracic; dorsal fins joined or, if separate, closely adjacent to one another.....	21
20a. (19a) Dorsal fin with 4 thick spines; anal fin with 2-3 spines; adipose eyelids present	Mullets – Mugilidae
20b. (19a) Dorsal fin with 4 to 8 thin spines; anal fin with 1 spine; adipose eyelids absent	Silversides – Atherinopsidae
21a. (19b) One nostril (nare) on each side of head; lateral line interrupted	
.....	Cichlids – Cichlidae
21b. (19b) Two nostrils (nares) on each side of head; lateral line complete, incomplete, or absent	22
22a. (21b) Dorsal fin with > 23 fin rays; lateral line extends to tip of caudal fin	
.....	Drums – Sciaenidae
22b. (21b) Dorsal fin with < 23 fin rays; lateral line, if present, does not extend to tip of caudal fin.....	23
23a. (22b) Anal fin with 1 to 2 spines.....	Perches – Percidae
23b. (22b) Anal fin with 3 to 8 spines	24
24a. (23b) Posterior margin of operculum with a sharp spine; spiny and soft dorsal fin separate or only slightly connected; pseudobranchium present and exposed.....	
.....	Temperate Basses – Moronidae
24b. (23b) Posterior margin of operculum without a sharp spine; spiny and soft dorsal fins connected or with deep notch; pseudobranchium covered or absent.....	24
25a. (24b) Lateral line present or incomplete	Sunfishes – Centrarchidae
25b. (24b) Lateral line absent	Pygmy Sunfishes – Eleotridae

KEY TO THE SPECIES

FAMILY PETROMYZONTIDAE – lampreys

Ichthyomyzon gagei

FAMILY POLYODONTIDAE—paddlefishes

Polyodon spathula

FAMILY LEPISOSTEIDAE—gars

1a. Large teeth in upper jaw in parallel rows on each side*Atractosteus spatula*

1b. Large teeth in upper jaw one row, although another non-parallel row might be present2

2a. (1b) Beak long and narrow, least width goes about 12 to 20 times in length; width of beak at nostrils < eye diameter; snout > $\frac{2}{3}$ of head length..... *Lepisosteus osseus*

2b. (1b) Beak short and blunt, least width goes about 5 to 7 times in length; width of beak at nostrils > eye diameter; snout < $\frac{2}{3}$ of head length *Lepisosteus oculatus*

FAMILY AMIIDAE—bowfins

Amia calva

FAMILY ANGUILLIDAE—freshwater eels

Anguilla rostrata

FAMILY CLUPEIDAE—herrings

1a. Twenty-nine to 33 anal fin rays; mouth subterminal and below level of middle of eye; black shoulder spot $\geq$ pupil of eye *Dorosoma cepedianum*

1b. Twenty-four to 28 anal fin rays; mouth terminal and at level of eye; black shoulder spot < pupil of eye*Dorosoma petenense*

FAMILY CYPRINIDAE - minnows

1a. More than 15 soft rays on dorsal fin; dorsal and anal fins each with a strong serrated spine2

1b. Fewer than 10 soft rays on dorsal fin; dorsal and anal fins without spine.....3

2a. (1a) Upper jaw with two pairs of barbels.....	<i>Cyprinus carpio</i>
2b. (1a) Upper jaw without barbels.....	<i>Carassius auratus</i>
3a. (1b) Anal fin near caudal fin, distance from snout to origin of anal fin is > 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth with prominent parallel grooves	<i>Ctenopharyngodon idella</i>
3b. (1b) Anal fin not noticeably near caudal fin: distance from snout to origin of anal fin is < 2.5 times the distance from origin of anal fin to base of caudal fin; pharyngeal teeth without prominent parallel grooves	4
4a. (3b) Intestine wound spirally around swim bladder; keratinous ridge on lower jaw	<i>Campostoma anomalum</i>
4b. (3b) Intestine not wound spirally around swim bladder; keratinous ridge of lower jaw hardly evident.....	5
5a. (4b) Abdomen behind pelvic fins with a fleshy keel lacking scales; lateral line greatly decurved, distance between anterior lateral line scale and ventral most lateral line scale is > 3 scales in height.....	<i>Notemigonus crysoleucas</i>
5b. (4b) Abdomen behind pelvic fin with scales; lateral line not greatly decurved, lateral line descends < 3 scales ventrally from highest point	6
6a. (5b) With maxillary barbels, might be small and not observable without opening the mouth or with magnification.....	7
6b. (5b) Without maxillary barbels	8
7a. (6a) Mouth terminal; distinct black spot located anteriorly on dorsal fin; pharyngeal teeth on main row 5-4 or 5-5.....	<i>Semotilus atromaculatus</i>
7b. (6a) Mouth subterminal or inferior; no distinct black spot on dorsal fin; pharyngeal teeth on main row 4-4	<i>Macrhybopsis hyostoma</i>
8a. (6b) Thick lower lip at corners, mouth noticeably ventral; black spot at base of caudal fin	<i>Phenacobius mirabilis</i>
8b. (6b) Lower lip thin or not noticeably thick; with or without black spot at base of caudal fin.....	9
9a. (8b) Predorsal scales appear crowded, smaller than scales on lateral body or appear as overlapping scales; black spot in the middle, anterior portion of the dorsal fin.....	10

9b. (8b) Predorsal scales not crowded; without black spot in the middle, anterior portion of the dorsal fin	11
10a. (9a) Caudal spot, if distinct, continuous with mid-lateral stripe; lateral line incomplete; intestine long, more than twice the standard length.....	<i>Pimephales promelas</i>
10b. (9a) Caudal spot distinct from mid-lateral stripe; lateral line complete, intestine forming a short S-shaped loop	<i>Pimephales vigilax</i>
11a. (9b) Long intestine in a flat coil.....	<i>Hybognathus nuchalis</i>
11b. (9b) Short S-shaped intestine	12
12a. (11b) Moderately decurved lateral line; diamond-shaped scales; dark shoulder patch present; melanophores concentrated between rays of dorsal and anal fins	13
12b. (11b) Lateral line incomplete, complete-straight, or complete-slightly decurved; scales not noticeably diamond-shaped; without dark shoulder patch; melanophores concentrated along rays of dorsal and anal fins	14
13a. (12a) Sub-terminal mouth; caudal fin base with a caudal spot larger than eye; no shoulder patch	<i>Cyprinella venusta</i>
13b. (12a) Terminal mouth; no caudal spot	<i>Cyprinella lutrensis</i>
14a. (12b) Distinct and separate black dash at base of dorsal fin; apparent when viewed from above; pharyngeal teeth count usually 0,4-4,0	15
14b. (12b) No distinct and separate black dash at base of dorsal fin; pharyngeal teeth count usually 1,4-4,1 or 2,4-4,2	18
15a. (14a) Lateral line scales markedly elevated (taller than wide) anteriorly, elevated scale height 2 to 5 times scale width.....	16
15b. (14a) Lateral line scales not markedly elevated anteriorly, scale height 1 to 2 times scale width	17

- 16a. (15a) Dorsal and lateral body with melanophores outlining scales; with pronounced black lateral stripe; dorsal fin height goes 2.1 or more times in pre-dorsal length; infraorbital canal complete *Notropis volucellus*
- 16b. (15a) Dorsal and lateral body with sparse melanophores; scales outlined with melanophores are rare; pre-dorsal black spot is prominent and distinct from mid-dorsal stripe; dorsal fin height goes 2.0 or fewer times in pre-dorsal length; infraorbital canal incomplete *Notropis buchanani*
- 17a. (15b) Eye large, eye diameter is > snout length *Notropis stramineus*
- 17b. (15b) Eye small, eye diameter is < snout length *Notropis sabinae*
- 18a. (14b) Depressed dorsal fin longer than head *Hybopsis amnis*
- 18b. (14b) Depressed dorsal fin shorter than head 19
- 19a. (18b) Mouth is sub-terminal; pharyngeal teeth are 0,4-4,0 *Notropis atrocaudalis*
- 19b. (18b) Mouth is terminal; pharyngeal teeth are 1,4-4,1 or 2,4-4,2 or 5-5 20
- 20a. (19b) Dorsal fin origin opposite or anterior to pelvic fin origin 21
- 20b. (19b) Dorsal fin origin posterior to pelvic fin origin 25
- 21a. (20a) Prominent mid-lateral stripe, extending through eye 22
- 21b. (20a) No prominent mid-lateral stripe present 24
- 22a. (21a) Pharyngeal teeth 5-5; mouth small and almost vertical *Opsopoeodus emiliae*
- 22b. (21a) Pharyngeal teeth are 1,4-4,1 or 2,4-4,2; mouth large and oblique 23
- 23a. (22b) Usually 8 anal fin rays; inside of mouth with black melanophores; dorsal fin insertion is opposite to pelvic fin insertion *Notropis chalybaeus*
- 23b. (22b) Usually 7 anal fin rays; inside of mouth without black melanophores; dorsal fin insertion is anterior to pelvic fin insertion *Notropis texanus*
- 24a. (21b) Usually 8 anal fin rays; head is narrow, depth at occiput more than width at occiput *Notropis shumardi*
- 24b. (21b) Usually 7 anal fin rays; head is wide, depth at occiput less than or equal to width at occiput *Notropis potteri*

25a. (20b) Moderate-sized scales, ≤ 40 lateral line scales, < 24 predorsal scales	
.....	<i>Notropis atherinoides</i>
25b. (20b) Small scales, ≥ 41 lateral line scales, > 25 predorsal scales.....	26
26a. (25b) Dorsal fin with black melanophores extending from mid-dorsal stripe into the anterior fin ray; edges of the anterior dorsolateral scales are outlined with black melanophores, producing chevron pattern.	<i>Lythrurus umbratilis</i>
26b. (25b) Dorsal fin with black melanophores not extending from mid-dorsal stripe into the anterior fin ray, lacks chevron pattern	<i>Lythrurus fumeus</i>

FAMILY CATOSTOMIDAE—suckers

1a. Dorsal fin long, base $>$ than $\frac{1}{3}$ of standard length; 22 to 30 dorsal fin rays	2
1b. Dorsal fin short, base $<$ than $\frac{1}{4}$ of standard length; 4 to 18 dorsal fin rays	4
2a. (1a) Small scales, lateral line scales > 50 ; eye closer to back of head than to tip of snout; head abruptly more slender than body; papillose lips.....	<i>Cycleptus elongatus</i>
2b. (1a) Large scales, lateral line scales < 45 ; eye closer to tip of snout than back of head; plicate lips	3
3a. (2b) Subopercle triangular, broadest toward base; knob present at tip of lower lip; blunt snout, forming level with eye	<i>Carpionodes carpio</i>
3b. (2b) Subopercle semicircular, broadest towards middle; knob absent at tip of lower lip; rounded snout, forming below level of eye	<i>Ictiobus bubalus</i>
4a. (1b) Lateral line complete and well developed; air bladder with 3 chambers	<i>Moxostoma poecilurum</i>
4b. (1b) Lateral line incomplete or absent; air bladder with 2 chambers	5
5a. (4b) Lateral line incomplete; rows of spots.....	<i>Minytrema melanops</i>
5b. (4b) Lateral line absent	6
6a. (5b) Scales larger, lateral scale count 34 to 37; eye larger, eye length $\frac{1}{2}$ of snout length; dorsal fin rays 11 or 12; back with crescentic scale marks.....	<i>Erimyzon sucetta</i>
6b. (5b) Scales smaller, lateral scale count 39 to 43; eye smaller, eye length $< \frac{1}{2}$ of snout length); dorsal fin rays 9 or 10; back without crescentic scale marks	<i>Erimyzon claviformis</i>

FAMILY CHARACIDAE—characins

Astyanax mexicanus

FAMILY ICTALURIDAE—bullhead catfishes

- 1a. Adipose fin joined to the caudal fin or separated by a shallow notch.....2
- 1b. Adipose fin free at tip, not joined to caudal fin3

- 2a. (1a) Mouth terminal; pectoral fin spine not serrated; lower lip and chin not heavily speckled with black pigment.....*Noturus gyrinus*
- 2b. (1a) Mouth sub-terminal; pectoral spine serrated; lower lip and chin heavily speckled with black pigment.....*Noturus nocturnus*

- 3a. (1b) Head dorso-ventrally compressed; mouth terminal to superior . *Pylodictis olivaris*
- 3b. (1b) Head rounded; mouth subterminal4

- 4a. (3b) Caudal fin rounded or shallowly emarginate.....5
- 4b. (3b) Caudal fin deeply forked6

- 5a. (4a) Chin barbels completely or partially black; anal fin rays 17 to 24; anal fin broadly rounded*Ameiurus melas*
- 5b. (4a) Chin barbels white or yellow; anal fin rays 24 to 27; margin of anal fin generally straight.....*Ameiurus natalis*

- 6a. (4b) Anal fin rays 30 to 36; anal fin free margin is straight; medial keel-like ridge anterior to dorsal fin forms humped back appearance*Ictalurus furcatus*
- 6b. (4b) Anal fin rays 22 to 29; anal fin free margin is rounded; no humped back appearance.....*Ictalurus punctatus*

FAMILY LORICARIIDAE—suckermouth catfishes

- 1a. Light spots on a dark background*Pterygoplichthys anisitsi*
- 1b. Dark spots on a light background *Pterygoplichthys disjunctivus*

FAMILY SALMONIDAE—salmons

Oncorhynchus mykiss

FAMILY ESOCIDAE—pikes and pickerels

Esox americanus

FAMILY APHREDODERIDAE—pirate perch

Aphredoderus sayanus

FAMILY MUGILIDAE—mulletts

1a. Lower jaw rounded, without a symphyseal knob; lower limb of 1st gill arch with 17 to 20 gill rakers; no adipose eyelid; scales ctenoid*Agonostomus monticola*

1b. Lower jaw angular, with a prominent symphyseal knob; lower limb of 1st gill arch with 25 to 60 gill rakers; adipose eyelid well developed in adults; scales cycloid in young, ctenoid in adults.*Mugil cephalus*

FAMILY ATHERINOPSIDAE—New World silversides

1a. Scales small, > 60 scales in lateral series, jaws produced into a short beak; snout length > eye length; > 20 anal fin rays*Labidesthes sicculus*

1b. Scales large, < 50 scales in lateral series; jaws not produced into a beak; snout length ≤ eye length; < 20 anal fin rays2

2a. (1b) Scales ctenoid, rough to the touch; double pairs of black spots on dorsum; bases of dorsal and anal fin covered with scales*Membras martinica*

2b. (1b) Scales cycloid, smooth to the touch; dorsum with crosshatching, but not double pairs of black spots; bases of dorsal and anal fins not covered with scales; horizontal distance between spinous dorsal and anal fin origin less than 7% of standard length.....*Menidia audens*

FAMILY FUNDULIDAE—topminnows

1a. More than 40 longitudinal scale rows; dark vertical barring; gill slit not extending dorsal to uppermost pectoral fin ray*Fundulus zebrinus*

1b. Fewer than 40 longitudinal scale rows; gill slit extending dorsal to uppermost pectoral fin ray2

2a. (1b) Body with a distinct black lateral band3

2b. (1b) Body without a distinct black lateral band4

- 3a. (2a) Distinct black spots on anterior dorso-lateral region are as pronounced as lateral stripe; distinct black spots throughout dorsal and caudal fins *Fundulus olivaceus*
- 3b. (2a) Faint black spots on anterior dorso-lateral region are not as pronounced as lateral stripe; distinct black spots near base of dorsal and caudal fins.....*Fundulus notatus*
- 4a. (2b) Red to dark spots in multiple rows longitudinally along lateral sides; usually with dark subocular bar*Fundulus blairae*
- 4b. (2b) Body mottled, barred or irregularly spotted; no dark subocular bar
.....*Fundulus chrysotus*

FAMILY CYPRINODONTIDAE—pupfishes

Cyprinodon variegatus

FAMILY POECILIIDAE—livebearers

- 1a. Origin of dorsal fin anterior to anal fin origin; intestinal canal long with many convolutions*Poecilia latipinna*
- 1b. Origin of dorsal fin posterior to anal fin origin; intestinal canal short with few convolutions*Gambusia affinis*

FAMILY MORONIDAE—temperate basses

- 1a. Dorsal fins united at base; 2nd and 3rd anal fin spines approximately equal in length; no teeth on tongue; 9 to 10 anal fin soft rays; stripes along sides usually sharply broken and offset above front of anal fin *Morone mississippiensis*
- 1b. Dorsal fins separated; 2nd anal fin spine < 3rd; base of tongue with teeth; 11 to 13 anal fin soft rays; stripes along sides usually continuous2
- 2a. (1b) Body depth goes < 3 times in standard length; teeth in single patch on back of tongue.....*Morone chrysops*
- 2b. (1b) Body depth goes > 3 times in standard length; teeth in 2 parallel patches on back of tongue*Morone saxatilis*

FAMILY CENTRARCHIDAE—sunfishes

- 1a. Five to 8 anal spines2
- 1b. Three anal spines.....4

2a. (1a) Eleven to 13 dorsal fin spines	<i>Centrarchus macropterus</i>
2b. (1a) Six to 8 dorsal fin spines	3
3a. (2b) Dorsal fin set back on body, length of dorsal fin base < distance from its origin to posterior margin of eye; lateral body with wide to narrow dorsal black bands; ≤ 6 dorsal spines.....	<i>Pomoxis annularis</i>
3b. (2b) Dorsal fin set forward on body, length of dorsal fin base equal to or greater than distance from its origin to posterior margin of eye; lateral body with checkerboard black and light pattern; ≥7 dorsal spines	<i>Pomoxis nigromaculatus</i>
4a. (1b) Body slender, body depth contained > 3 times into standard length.....	5
4b. (1b) Body deep, body depth contained < 3 times into standard length.....	6
5a. (4a) Dorsal fins narrowly joined at base forming a deep notch; upper jaw extends past posterior margin of eye in adults; mid-lateral stripe generally complete, rows of spots ventral to mid-lateral stripe faint and incomplete	<i>Micropterus salmoides</i>
5b. (4a) Dorsal fins broadly joined at base forming a shallow notch; upper jaw does not reach past posterior portion of eye; bases of soft dorsal and anal fins scaled	<i>Micropterus punctulatus</i>
6a. (4b) Teeth on tongue; head and opercle with 3 to 5 distinct dark and light longitudinal stripes; red spot on posterior margin of opercle flap in fresh specimens....	<i>Lepomis gulosus</i>
6b. (4b) No teeth on tongue; head and opercle lacking distinct dark and light longitudinal stripes	7
7a. (6b) Pectoral fins long and pointed, reach anterior portion of eye or beyond when bent forward.....	8
7b. (6b) Pectoral fins short and rounded, do not reach past eye when bent forward.....	10
8a. (7a) Opercle flap stiff to its margin, posterior margin either red or orange in live specimens	<i>Lepomis microlophus</i>
8b. (7a) Opercle flap flexible, posterior margin not red or orange in live specimens	9

- 9a. (8b) Opercle flap black to the margin; black spot on posterior base of soft dorsal fin*Lepomis macrochirus*
- 9b. (8b) Opercle flap outlined with thick white band; lacking black spot on posterior base of soft dorsal fin *Lepomis humilis*
- 10a. (7b) Black opercle flap stiff near the posterior margin with bone supporting all or majority of the flap.....11
- 10b. (7b) Black opercle flap flexible near the posterior margin without bone supporting majority of the flap.....13
- 11a. (10a) Lateral line incomplete; smaller individuals with black spot surrounded by white margin on posterior base of soft dorsal fin *Lepomis symmetricus*
- 11b. (10a) Lateral line complete; black spot, if present, on posterior base of soft dorsal fin without white margin12
- 12a. (11b) Body elongated with black spot on posterior base of soft dorsal fin.....
.....*Lepomis cyanellus*
- 12b. (11b) Body rounded without black spot on posterior base of soft dorsal fin; lateral body with alternating stripes formed from black and red spots..... *Lepomis miniatus*
- 13a. (10b) Opercle flap black to the posterior margin; opercle flap is thin near the opercle bone with the narrowest width of the flexible portion of the flap about the same diameter of the eye pupil.....*Lepomis auritus*
- 13b. (10b) Opercle flap black and surrounded by white on the posterior margin; opercle flap is wide with narrowest width of the flexible flap is about two times the diameter of the eye pupil.....14
- 14a. (13b) Twelve pectoral fin rays, 3 to 5 cheek scales; opercle flap often with white pigment form speckles, distinct red spots (white in preserved specimens) along lateral line.....*Lepomis marginatus*
- 14b. (13b) Thirteen to 15 pectoral fin rays, 5 to 7 cheek scales; opercle flaps with red or white margin; 13 to 15 pectoral fin rays *Lepomis megalotis*

FAMILY PERCIDAE—perches

- 1a. Body depth contained in standard length > 7 times*Ammocrypta vivax*
- 1b. Body depth contained in standard length < 7 times2

2a. (1b) Snout conical, extends beyond upper lip; body with ≥ 14 black vertical bars	3
2b. (1b) Snout less conical, does not extend beyond upper lip; body with < 14 black vertical bars or with a pattern other than vertical bars.....	4
3a. (2a) Body with thick vertical bars, bars alternate in length from long to short; 9 to 10 long bars.....	<i>Percina carbonaria</i>
3b. (2a) Body with 14 to 16 thin vertical bars of similar length	<i>Percina macrolepida</i>
4a. (2b) Sides of body with large black blotches; midline of abdomen naked or with enlarged scales	5
4b. (2b) Sides of body without large black blotches; scales on abdomen normal	6
5a. (4a) Nape unscaled; blotches on sides of body are rectangle shaped and might appear connected	<i>Percina maculata</i>
5b. (4a) Nape scaled; blotches on sides of body not rectangle shaped	<i>Percina sciera</i>
6a. (4b) Lateral line short, < 6 pored scales; single row of horizontal dashes present	<i>Etheostoma proeliare</i>
6b. (4b) Lateral line long (complete or incomplete), > 6 pored scales; if horizontal dashes present, accompanied by vertical bars	7
7a. (5b) Lateral line arched upward	<i>Etheostoma gracile</i>
7b. (5b) Lateral line straight.....	8
8a. (6b) Lateral body with distinct series of M-shaped pigments; snout rounded and blunt	<i>Etheostoma chlorosoma</i>
8b. (6b) Lateral body without distinct series of M-shaped pigments; snout not noticeably rounded and blunt	9
9a. (8b) Lateral region with mottling bisected by a light colored lateral stripe.....	<i>Etheostoma parvipinne</i>
9b. (8b) Lateral region without mottling bisected by a light colored lateral stripe; lateral region with a series of dashes followed by a series of vertical bars; throat of live males orange.....	<i>Etheostoma spectabile</i>

FAMILY SCIAENIDAE—drums

Aplodinotus grunniens

FAMILY ELASSOMATIDAE—pygmy sunfishes

Elassoma zonatum

FAMILY CICHLIDAE—cichlids

1a. Anal fin spines 5 to 6*Herichthys cyanoguttatus*

1b. Anal fin spines < 5 (usually 3)..... *Oreochromis aureus*

FAMILY ACHIRIDAE—American soles

Trinectes maculatus

Appendix 2.1 List of fish species found in raw data with number of drainages sampled and sample size. Drainages represent a major drainage basin with a Hydrologic Unit Code of 4

Family	Species	Drainages found	N
Petromyzontidae	<i>Ichthyomyzon gagei</i>	1	169
Lepisosteidae	<i>Atractosteus spatula</i>	5	27
	<i>Lepisosteus oculatus</i>	8	374
	<i>Lepisosteus osseus</i>	7	421
	<i>Lepisosteus platostomus</i>	1	4
	<i>Amia calva</i>	2	7
Amiidae	<i>Amia calva</i>	2	7
Hiodontidae	<i>Hiodon alosoides</i>	1	1
Anguillidae	<i>Anguilla rostrata</i>	1	6
Clupeidae	<i>Dorosoma cepedianum</i>	7	4,512
	<i>Dorosoma petenense</i>	5	2,251
Cyprinidae	<i>Campostoma anomalum</i>	6	5,356
	<i>Cyprinella lepida</i>	1	614
	<i>Cyprinella lutrensis</i>	8	265,147
	<i>Cyprinella proserpina</i>	1	3,750
	<i>Cyprinella venusta</i>	8	65,309
	<i>Cyprinus carpio</i>	8	553
	<i>Dionda argentosa</i>	1	9,496
	<i>Dionda diaboli</i>	1	1,009
	<i>Dionda episcopa</i>	2	1,630
	<i>Dionda nigrotaeniata</i>	2	5,540
	<i>Dionda serena</i>	1	2,297
	<i>Hybognathus hayi</i>	1	2
	<i>Hybognathus nuchalis</i>	2	1,034
	<i>Hybognathus placitus</i>	2	6,089
	<i>Hybopsis amnis</i>	2	3
	<i>Luxilus chrysocephalus</i>	1	728
	<i>Lythrurus fumeus</i>	6	3,844
	<i>Lythrurus umbratilis</i>	2	356
	<i>Macrhybopsis aestivalis</i>	1	353
	<i>Macrhybopsis australis</i>	1	483
	<i>Macrhybopsis hyostoma</i>	4	2,401
	<i>Macrhybopsis marconis</i>	2	1,528
	<i>Macrhybopsis tetranema</i>	1	762
	<i>Macrhybopsis storeriana</i>	2	10

	<i>Notemigonus crysoleucas</i>	5	210
	<i>Notropis amabilis</i>	4	28,528
	<i>Notropis atherinoides</i>	1	2,129
	<i>Notropis atrocaudalis</i>	3	2,999
	<i>Notropis bairdi</i>	1	6,387
	<i>Notropis braytoni</i>	1	3,716
	<i>Notropis buchanani</i>	6	8,937
	<i>Notropis chalybaeus</i>	1	228
	<i>Notropis chihuahua</i>	1	13
	<i>Notropis girardi</i>	1	2,314
	<i>Notropis jemezianus</i>	1	5
	<i>Notropis oxyrhynchus</i>	1	1
	<i>Notropis potteri</i>	1	29
	<i>Notropis sabinae</i>	2	1,371
	<i>Notropis shumardi</i>	3	2,972
	<i>Notropis stramineus</i>	7	3,562
	<i>Notropis texanus</i>	6	1,237
	<i>Notropis volucellus</i>	4	13,944
	<i>Opsopoeodus emiliae</i>	6	392
	<i>Phenacobius mirabilis</i>	2	122
	<i>Pimephales promelas</i>	6	706
	<i>Pimephales vigilax</i>	8	83,195
	<i>Platygobio gracilis</i>	1	192
	<i>Rhinichthys cataractae</i>	1	40
	<i>Semotilus atromaculatus</i>	2	1,054
Catostomidae	<i>Carpionodes carpio</i>	7	2,770
	<i>Cycleptus elongatus</i>	2	94
	<i>Erimyzon claviformis</i>	2	29
	<i>Erimyzon sucetta</i>	1	3
	<i>Ictiobus bubalus</i>	8	440
	<i>Minytrema melanops</i>	5	129
	<i>Moxostoma congestum</i>	4	1,754
	<i>Moxostoma poecilurum</i>	2	73
Characidae	<i>Astyanax mexicanus</i>	5	14,395
Ictaluridae	<i>Ameiurus melas</i>	7	63
	<i>Ameiurus natalis</i>	8	391
	<i>Ictalurus furcatus</i>	7	1,550
	<i>Ictalurus lupus</i>	2	235
	<i>Ictalurus punctatus</i>	9	6,587
	<i>Noturus gyrinus</i>	5	229
	<i>Noturus nocturnus</i>	3	172

	<i>Noturus phaeus</i>	1	410
	<i>Pylodictis olivaris</i>	8	1,067
Loricariidae	<i>Hypostomus plecostomus</i>	1	851
